So how can social scientists nurture the development of multicultural psychology? A discipline hoping to understand, and value diversity must identify and eliminate overt and covert conformity, prejudice, and oppression in its institutions and members. Additionally, programmatic multicultural programs with goals of recognizing, respecting and learning from individual and cultural similarities and differences will combat the present day mythical social ideals and stereotypes resulting in the exploitation, coercion, and oppression of all people. While difficulties exist in eradicating xenophobia and notions of individual, group, and cultural superiority/inferiority, these obstacles will be outweighed by the ultimate rewards of all people having the opportunity to develop into their fullest personal, social, and racial–cultural potential. Thus, educators will need to continue developing training programs to incorporate cognitive/affective racial–cultural learning so counselors will be prepared to realistically work with inherent human variation. By clarifying ones' own racial and cultural identities and developing a self-acceptance, counselors will be able to respectfully and effectively work with all racial–cultural groups. Thus, the growth of multicultural psychology will depend on those who teach, research, and practice to continually develop themselves as racial–cultural people. Institutional support will provide the fertile ground necessary to do this work of moving beyond ignorance, tolerance, to meaningful understanding. Ultimately, the results will be a world where multicultural psychology is a lifestyle lending itself to an openness of understanding *who people are* rather than *what they are imagined to be*.

Editor's Note

Since the original publication of Dr Ota Wang's article, the focus in the counseling and larger psychological professions on cultural competence in interventions and a truly cross-cultural psychology has grown dramatically. A now-famous essay (Henrich et al., 2010) has made the point that modern psychology is to a large extent based on "The Weirdest People in the World," where WEIRD stands for Westernized, Educated, Industrialized, Rich, and Democratic – a rather exotic minority group judged by global standards. A useful starting point for readers wishing to access the more current literature on the topic is Roy Moodley and Stephen Palmer, 2006. The most widely cited text on the topic is David Matsumoto and Linda Juang, 2013. Also helpful: J.G. Ponterotto, 2010, Gerstein, L.H. (2011), Pedersen et al. (2008), and Sue, D.W. (2007).

One intervention strategy that responds to the call for cultural competence is that of matching clients and therapists on relevant ethnic, racial, and cultural criteria. An important review essay evaluating the effectiveness of this approach is Raquel R. Cabral and Timothy B. Smith, 2011.

Abstract

Counseling psychology is a specialty field within the broader discipline of psychology. The distinctiveness of the specialty is clarified in terms of its five unifying themes: focus on intact personalities; focus on human strengths; emphasis on relatively brief interventions; emphasis on person–environment interactions; and emphasis on education, career development, and environments. In terms of basic features, counseling psychology is a doctoral level field that strongly endorses the scientist-practitioner model and pays close attention to human diversity. Typical roles and functions of counseling psychologists are noted. Regarding scientific inquiry, key research issues and topics are discussed: central methodological developments; major research findings and theories in counseling and psychotherapy; multicultural factors in counseling interventions; career development and intervention; research and theory on training in both practice and science; and the fundamental scientific emphasis on healthy functioning and human effectiveness.

This article is about the science and profession of counseling psychology. Key distinguishing features of counseling psychology are described, as are the main roles and work settings of counseling psychologists. In addition, basic areas of scientific inquiry are discussed.

Counseling psychology is a specialty field within the broader discipline of psychology. This specialty is related to, but also different from, several other psychology specialties that are often characterized by the term 'applied.' The psychology specialties to which counseling psychology is most closely related are clinical, community, school, and industrial/organizational psychology. Although each of these fields seeks to study and understand human behavior empirically, the fields also share the mission of applying scientific understandings to the solution of human problems and the betterment of peoples' lives. It is in this sense that they may be termed applied specialties.

As is the case with any field or specialty, counseling psychology originated from a broad matrix of social, economic, and psychological forces. Its beginnings may be traced to the early part of the twentieth century. However, the designation of counseling psychology as a specialty within the American Psychological Association (APA) first occurred in 1952. For historical analyses, the reader is referred to Gelso and Fretz (2000).

Counseling Psychology: Distinctiveness and Diversity

In this section, the features that make counseling psychology a unique specialty within psychology, as well as the breadth and diversity of this field, are described.

The Unifying Themes of Counseling Psychology

As a way of clarifying the features that make for its distinctiveness, Gelso and Fretz (2000) proposed five unifying themes of counseling psychology. These themes, which have received substantial endorsement in the field, are briefly described below. The themes are best viewed as central tendencies, for there is also great variability around each theme.

The first unifying theme is a focus on intact, as opposed to profoundly disturbed, personalities. In earlier days, counseling psychology was thought of as a field that focused only on 'normal' problems. Today, psychologists trained in this field-work with clients at all levels of disturbance. However, in comparison to other health service fields such as clinical psychology and psychiatry, counseling psychologists continue to work more with clients closer to the normal range, and to devote more time to issues of psychological health and wellness.

The second unifying theme is the focus on assets and strengths, regardless of clients' level of disturbance. Indeed, attention to strengths has been a hallmark of this specialty, and is most evident when counseling psychologists engage in preventive and developmental interventions, as opposed to remedial ones. Preventive and developmental interventions, rather than emphasizing emotional problems that have already emerged, seek to prevent problems and enhance growth. A few of the numerous examples of such interventions are enhancement treatments for couples who do well but want to improve further, career counseling for clients who want to understand fields that fit them best, and consultation with business organizations to help create healthy work environments.

The third unifying theme is emphasis on relatively brief interventions. Counseling psychologists engage in a wide range of interventions, for example, counseling, consultation, guidance. Also, many practitioners in this specialty conduct long-term psychotherapeutic treatments. However, a hallmark of the field has always been an emphasis on brevity. The use of the term 'counseling' is a reflection of this tendency, and currently popular brief therapies fit closely with such a counseling orientation. Generally, therapy lasting less than six months is seen as brief, although most counseling psychology interventions are of much briefer duration.

Emphasis on person–environment interactions is a fourth unifying theme. From its inception, counseling psychology has sought to balance the intrapsychic and the environmental, both in understanding development and in formulating interventions. Theories that have focused largely on intrapsychic explanations, such as psychoanalysis, have not had wide appeal. Current attention to the role of culture and multicultural issues is an example of counseling psychology's commitment to incorporating the role of situation and environment in understanding personality and development, and in providing effective interventions.

The final unifying theme, perhaps more than the others, reflects counseling psychology's distinctiveness. The field's emphasis on educational and career development and environments has often been seen as its most distinctive feature. Throughout its history, counseling psychologists have theorized about and empirically investigated issues around career choice, problems, interests, development, and interventions.

Fundamental Features of the Field

There are certain features of this field that, while not necessarily distinctive, are so fundamental as to require mention. First, counseling psychology is a doctoral level field in the USA in that the large majority of US psychologists who use the title counseling psychologist, and who join the Division of Counseling Psychology of APA, hold a doctoral degree. Second, since the specialty's beginnings, it has strongly endorsed the scientist-practitioner model of training, which dictates that doctoral programs seek to train students as scientific researchers as well as practitioners of counseling psychology.

A third fundamental feature of the field is its attention to issues of culture, multiculturalism, and diversity. Although all fields within psychology have begun to pay attention to diversity in terms of race/ethnicity, sexual orientation, gender, religious beliefs, and physical disability, counseling psychology has been at the forefront in these areas for many years. Attention to issues of diversity pertains to, for example, recruitment of doctoral students and faculty, empirical research and theory, and counseling practice. The fundamental emphasis on culture and diversity in the specialty is evidenced in chapters in the most recent edition of the *Handbook of Counseling Psychology* (Brown and Lent 2000) on the role of race and social class in development; gender, sexuality, and sexual orientation; gender issues in counseling; and models of multicultural counseling.

The Roles and Functions of Counseling Psychologists

Information on where counseling psychologists work and what they do is basic to understanding this specialty. Gelso and Fretz (2000) present data on job settings indicating that over half the counseling psychologists who were members of the Division of Counseling Psychology (DCP) of APA were employed in college and university settings, either in academic departments (35%) or counseling centers (17%). A major change in recent years has been the increased appeal of independent practice, with approximately 20% of DCP members claiming this as their primary job. Furthermore, since many counseling psychologists who are in independent practice do not join the DCP, the 20% figure is likely a significant underestimate.

The remainder of counseling psychologists are distributed across a wide range of job settings, including hospitals (e.g., general, psychiatric, Veterans Administration), clinics, government agencies, business and industry, and rehabilitation facilities. Surveys over several decades indicate that these job patterns have been generally quite consistent, except for the increase in independent practice since about the mid-1980s, and a decline in the numbers of counseling psychologists in Veterans Administration centers.

Regarding job activities, the most basic finding of all surveys is that counseling psychologists are involved in an extensive range of activities. A significant number devote at least some of their work time to counseling and psychotherapy (individual, group, couples, family); consultation; psychological testing, assessment, and evaluation; research and writing; teaching, training, and supervision; and administration (Gelso and Fretz 2000). At the same time, the activities performed by the greatest numbers for the greatest amount of time are counseling and psychotherapy.

Scientific Inquiry

The major areas of theory and research in counseling psychology reflect the above discussion. Below are described key scientific issues and topics in this field.

Methodological Considerations

A fundamental quality of science in counseling psychology since the late 1970s has been its emphasis on diversity of research methods and approaches (Heppner et al. 2000). As pointed to by most reviewers, beginning in the late 1970s, there has been an increasing press to incorporate research methods that go beyond the 'received view,' for example, quantitative-experimental research.

Within the context of this methodological pluralism, two notable patterns may be seen. First, stemming from post-modern thought that is evident in all scholarly disciplines, there has been a growing interest in the use of qualitative research approaches (Morrow and Smith 2000). Such approaches use verbal or even visual rather than quantitative data, gather data by observing and listening to what people do and say, and present results in the form of verbal descriptions and theories rather than statistics.

A second pattern actually moves in the opposite direction from qualitative research. That is, there has been a major increase in the use of highly sophisticated quantitative methods. Multivariate statistical methods now appear to be as common as univariate approaches. Especially prominent are techniques that seek to permit causal inferences from correlational data, for example, structural equation modeling.

Counseling and Therapy: Theory and Research

Regarding psychological interventions, counseling psychologists study essentially the same therapeutic process and outcome questions as do other applied counseling fields, for

example, clinical psychology. After many years of outcome research, it is clear that, on the whole, therapy is effective; researchers now seek to discover what treatments are most effective when offered by what therapists for which clients experiencing what problems (Gelso and Fretz 2000).

Beyond this general statement, there are some therapy theories and topics that have been most influential in counseling psychology. Broadly speaking, cognitive-behavioral and experiential-humanistic theories of counseling have had the greatest impact (Heesacker 2000). As part of the strong cognitive-behavioral influence, theories such as Albert Ellis' rational-emotive behavior therapy, Aaron Beck's cognitive therapy, and Albert Bandura's social cognitive theory have been particularly appealing to researchers and practitioners. Psychoanalytic theories have historically been less attractive to counseling psychologists, partly because these theories have conflicted with some of the major emphases of the field (e.g., strengths and assets, brevity, environmental influences). Fundamental paradigmatic changes in psychoanalysis in recent years, however, have made some of its theories (e.g., psychoanalytic self-psychology) more appealing (Gelso and Fassinger 1992). Social psychological conceptions have also had great appeal in recent decades. Theories such as social influence theory have been creatively extrapolated to counseling and therapy, and their propositions extensively investigated (Heesacker 2000).

Multicultural Counseling and Research

As noted, counseling psychologists have closely attended to diversity for many years. Since the early 1980s, however, there has been a mushrooming of theory and research on counseling and development as related to culture and diversity. The topic that has gathered the most scientific momentum is that of race and ethnicity in psychological development and treatment. This momentum is evidenced in the form of the high rate of articles on race, ethnicity, and culture in leading journals; major handbooks on the topic (e.g., Ponterotto et al. 1995); the creation of new journals; and the publication of texts and significant chapters. Although race and ethnicity are the most frequently studied topics under the umbrella of diversity, there are others. In recent years there has been a significant surge of research on gay, lesbian, and bisexual issues in counseling and development. The study of gender, which may be placed within the diversity category, has been central in counseling psychology for nearly three decades (Heppner et al. 2000).

Career Development and Intervention

Whereas the development of theory and research on diversity topics has increased at a dramatic pace in recent decades, the topic of career development and intervention has been a mainstay of counseling psychology since its inception. Many consider this the strongest and most empirically mature area within the specialty (Heppner et al. 2000). As part of this strength and maturity, robust theories of career development and choice guided theory and practice over many years (e.g., theories by Holland, Super, and Krumboltz). There exist a number of journals, handbooks, and texts aimed at studying and elaborating career development and intervention processes. In keeping with the diversity movement, recent decades have witnessed much attention to career development in the lives of marginalized people. The study of career development and intervention in womens' lives has been particularly prominent over many years.

Training in Practice and Science

The tandem topics of counselor training and researcher training are key areas of investigation. Of the two, counselor training and supervision has had the longer life. In particular, theory and research on the process and outcome of counselor supervision have been prominent since the late 1970s. Especially notable have been developmental models of counseling supervision, wherein therapists are theorized as developing in0 certain stages, and supervision approaches need to be matched to those stages (Stoltenberg et al. 1997). Regarding research training, theory and research have examined both person and research training environment factors that contribute to graduate students' and psychologists' interest in, sense of efficacy for, and production of research and science (Gelso and Lent 2000).

Healthy Functioning and Human Effectiveness

Research and theory in this general area are natural extensions of two key unifying themes described earlier: focus on intact personalities and attention to people's strengths. Although attention to positive qualities is a deep and widely shared part of the specialty, theory and research on the topic within counseling psychology had waned for a number of years, to the point that Gelso and Fassinger (1992) viewed this area as counseling psychology's 'unfulfilled promise.' However, there has been an upsurge of scientific attention to well functioning. The study of positive constructs such as subjective well-being, career self-efficacy, and problem solving all fit this thrust. So, too, does the emerging examination by counseling psychologists of biopsychosocial factors that promote positive physical health (Hoffman and Driscoll 2000).

Counterculture: 1960s and Beyond

Ralph W Larkin, The City University of New York, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article on counterculture begins with an exploration of the counterculture of the 1960s. The definition of the term 'counterculture' is examined and refined. The legacy of the counterculture of the 1960s is analyzed in light of subsequent social and cultural changes. The English revolution of the mid-seventeenth century is explored as an historical instance of a counterculture. The article concludes with a discussion of the relationship between social movements and countercultures.

In the fall of 1965, young people from the suburbs of San Francisco forsook their comfortable bedroom communities and migrated to the Haight-Ashbury district at the foot of Golden Gate Park to live lives at the edge of poverty. They panhandled for cash, wore secondhand clothes, and lived in 'crash pads' that had little more than mattresses as furniture. They were collectively known as 'hippies' (Cavan, 1972). Hippie culture was subversive of the dominant culture; if contemporary culture emphasized waste consumption, hippies lived with the bare necessities, plus, maybe an electric guitar with an amp system. When the Vietnam War escalated, hippies emphasized living in peace and cooperation. If the dominant culture emphasized the work ethic, hippies were ostensively unemployed. If sobriety and emotional constraint were the dominant norms, hippies were publicly stoned on drugs such as marijuana and lysergic acid diethylamide (LSD) and danced in the streets. If the American culture was sexually repressive, hippies engaged in a variety of tabooed sexual behaviors, including promiscuity, group sex, public intercourse, homosexual coupling, and public nudity (Yablonsky, 1968). Hippies were the precursors to what later came to be known in the English-speaking West as 'the counterculture.'

A year earlier, in the fall of 1964, across the bay at the University of California, the Berkeley Free Speech Movement (FSM) erupted (Freeman, 2004). Members of several protest groups returned to school from the Freedom Summer after registering black voters in the South in the face of white racist terrorism. When campus police confronted them and told them that they could not distribute political literature on campus property, they claimed that their rights to free speech were being abrogated. Based upon their training in nonviolent protest, they staged sit-ins and occupied the administration building; their protests spread throughout the campus. The FSM marked the beginning of the middle-class youth movement in America. The emergence of a dissident subculture in the Haight-Ashbury section of San Francisco among members of essentially the same social category a year later signaled a change in emphasis from overt politics to cultural conflict (Foss and Larkin, 1976).

What Is a Counterculture?

Before defining 'counterculture,' one must know what is meant by 'culture.' A general agreement exists among anthropologists that human culture includes the ideological realm of human behavior, including norms, values, patterns of behaviors, concepts of 'meaning,' and their embodiment in artifacts (Kroeber and Kluckhohn, 1952). Culture includes language, religion, and thought forms.

Complex societies, such as contemporary capitalist societies, contain dominant cultures and a variety of subcultures (Parsons, 1951). The dominant culture is almost always associated with the political and economic elite. Subcultures are at variance from the dominant culture on ethnic, social class, racial, age, sexual orientation, and other social differentiations. Subcultures exist within a larger multicultural context from the dominant culture, with which they share certain core values, but differ over significant points (Yinger, 1960). Most common subcultures are based upon ethnicity, such as African-American and Latino subcultures within the United States. However, there are other subcultures, such as gay 'queer' culture, and religious subcultures such as evangelicals, Jewish Hasidim, and Mormons. A counterculture, however, poses itself in *total opposition* to the dominant culture. It takes the values of the dominant culture and redefines them negatively.

The term 'counterculture' entered the sociological lexicon when social theorist Talcott Parsons (1951: p. 522) used it to describe deviant subcultures, such as delinquent gangs. Milton Yinger (1960), following Parsons, separated 'contraculture' from subcultures as a response to a frustrating environment, citing youth culture as an example. Youth culture tended to have socializing power over its members that contradicted some norms of the parent generation.

Yinger (1977) returned to the topic of counterculture in 1977. By that time, the middle-class youth movement (1964–70) was long over (Foss and Larkin, 1976). With the counterculture in retrospective view, he redefined counterculture as "a set of norms and values that sharply contradict the dominant norms and values of the society of which that group is part" (p. 833). No longer is the counterculture associated with delinquency and adolescent culture, but exists as a critique of the dominant culture.

Since the 1960s, scholars have found countercultures all over the world, within organizations, and in a variety of historical eras (Halldorf, 2010; Kolind, 2011; Morant, 2011; Viehe, 2011). Because the concept of counterculture emerged from within a social category in movement against dominant institutions, its use has been widespread without much consideration of its definition, which has been taken for

granted. Now that countercultures have been defined as a rejection of the dominant culture and exist within the context of a social movement, it must be defined what is meant by a social movement.

Foss and Larkin (1986) defined a social movement as

> the developing collective action of a significant portion of the members of a major social category, involving at some point the use of physical force or violence against members of other social categories, their possessions, or their institutionalized instrumentalities, and interfering, at least temporarily – whether by design or by unintended consequence – with the political and cultural reproduction of society. (p. 2)

All social movements have a cultural dimension; political action is by nature episodic. Typical forms of political action include elections, strikes, protests, civil disobedience, boycotts, insurrections, and so forth. These actions can occur both within and outside social movements. What differentiates social movements from isolated political actions is that movement collectivities have a shared culture that legitimizes their own behavior, identifies opposing institutions and social categories, redefining them as the enemy, and reinterprets social reality (Foss and Larkin, 1986). The movement culture provides the glue that holds the movement together. As the struggle between social movement participants and the opposition intensifies, the movement interpretation of reality tends to become increasingly radical, based upon the experience of the movement participants:

> When collective dissidence arises, the participants come to reject ever-larger portions of the hegemonic ideology. Social relations previously accepted as reasonable, inflexible, inexorable, and primordial now appear as contrived, unnatural, substantively irrational, parasitic, and senseless. [Movement participants'] own subsumption within the relations of exploitation and domination, formerly accepted as part of the natural order of things, is repudiated as unjust, arbitrarily imposed, and void of moral sanction. (Foss and Larkin, 1986: p. 73)

The reinterpretation of social reality that was inextricably tied to the middle-class youth movement formed the basis of the counterculture.

'The' Counterculture

The counterculture emerged in the mid-1960s as a self appellation among young people within the middle-class youth movement as politics merged with cultural issues. The issues of racism, collusion of higher education institutions with the military and corporate worlds in support of the Vietnam War, and *en loco parentis* regulations in colleges and universities fused with struggles over hair length, communal living, musical tastes, drug use, gender roles, and sexuality (Foss, 1972). At the height of the middle-class youth movement, there emerged a new social type, self-designated as the 'freak radical,' whose opposition to the dominant institutions was as much cultural as it was political, and whose critique of state-supported corporate capitalism was total. Political radical Abbie Hoffman (1968) under the pseudonym 'Free' offered social revolution as the meaningful alternative to the structure and ethos of the dominant society that emphasized hierarchy, bureaucracy, competition, upward mobility, the work ethic, and drugs of consciousness constriction (e.g., alcohol and barbiturates).

Countercultural radicals maintained a 'postscarcity' mentality (Bookchin, 1971) based upon their own experiences in an expanding and increasingly prosperous middle class. They perceived that society had reached a point at which the production of material goods was no longer an issue; inequitable distribution was. There was no need for humans to devote the majority of their waking hours obtaining the necessities of existence. Life was to be lived in loving communities that coalesced in a common cause of bringing down a corrupt social system. From the outside, capitalism in its contemporary form was a system that made no sense. Production had been liberated from the satisfaction of basic human needs and had become an end in itself. Humans had become harnessed to an increasingly frenetic system of production, distribution, and consumption of commodities that they had to be convinced they needed. This system of waste production for waste consumption alienated human beings from meaningful social participation, demanded participation in labor that had little redeeming social value, was ecologically destructive, required sexual repression, and drained life of its ecstatic and joyful dimension (Foss, 1972).

By the end of the summer of 1969, after the apocryphal countercultural event, the Woodstock Music Festival, the middle-class youth movement was showing clear signs of its demise (Foss and Larkin, 1976). At this point, the Women's Liberation Movement (WLM), which began as a response to the sexism of male movement participants (Morgan, 1970), was entering its most radical phase. Patriarchy was being diagnosed as the enemy of the liberation of women. The WLM gave a fresh new edge to the counterculture by emphasizing gender equality and promoting feminism. Women's values were offered as an alternative to the competitive, warlike, hierarchical, and patriarchal values of the hypermasculine dominant society. Radical feminists engaged in numerous activities designed to delegitimate patriarchy. They demanded equal pay for equal work; they disrupted the Miss America beauty pageant in 1968. They supported feminist candidates for political office. Feminists formed 'consciousness-raising groups,' analyzing sexist aspects of domestic relations and the sexual bias of the English language.

The Counterculture in the Postmovement Period

Social movements are episodic events that can last from a few weeks (e.g., Paris, France, May–June 1968) to decades (the English Revolution, 1640–60). Their consequences can be as varied as a return to the status quo *ante* or social revolution. When social movements end, the countercultures associated with them must be incorporated in some form into the dominant culture, even if the counterculture has resulted in a cultural revolution. That which was spontaneous becomes institutionalized. Oppositional elements that formerly defined

behaviors and organizations are blunted or eliminated (Foss and Larkin, 1976).

In the wake of a movement, especially a movement that ushered in a cultural revolution, such as the counterculture of the 1960s and early 1970s, movement participants were caught between lives they had rejected and a vision of an alternative life whose possibilities were being foreclosed. Foss and Larkin (1979) described this as a 'life construction crisis' for former social movement participants. In the early 1970s, there arose a plethora of groups that catered to the needs of social movement participants. These assumed the forms of authoritarian communes coalescing around a charismatic leader who controlled the lives of his followers (the Manson family, 'Spirit in Flesh' commune), mechanistic Marxist sects (Weather Underground, National Caucus of Labor Committees, October League, Revolutionary Union), Orientalist sects (Transcendental Meditation, Nichiren Shoshu, Hare Krishnas, Divine Light Mission), and Christian sects (Jesus Freaks, Children of God). In addition, a number of therapeutic cults arose promising surcease from psychological pain, including the Sullivanians on the Upper West Side of New York, and Werner Erhard's Erhard seminars training (est) therapy cult. Already existing organizations, such as Scientology and various evangelical Christian sects experienced a surge in membership consisting of former social movement participants.

In each case, the organization appropriated a fragment of the counterculture vision, such as psychological transcendence, actualizing one's potentials, or revolution, while simultaneously enforcing strict discipline over the membership's lives (Foss and Larkin, 1976, 1979). Sexual and drug abstinence were justified as sacrifices needed to further the revolution or achieve higher consciousness. As noted by several researchers (Judah, 1974; Petersen and Mauss, 1973; Robbins et al., 1975), these groups functioned as conduits from the dying counterculture back to conventional society while assuaging the pain in doing so.

The Legacy of the Counterculture

The counterculture revolutionized contemporary culture in five major ways: (1) deep suspicion of social institutions, especially institutions of the state; (2) the rise of consumer society; (3) the sexual revolution; (4) the emergence of new thought forms; and (5) the advent of the personal computer.

Since the 1960s, Americans' adherence and cohesion to major social institutions has declined quite dramatically, generating a crisis of legitimation. Lipset and Schneider (1983) traced an increase in alienation of Americans from major political, business, and labor organizations from the mid-1960s to 1981, the last year of available data for their analyses. Gallup poll data (2013) have suggested that for major American institutions, including the federal government, organized religion, medicine, news organizations, and public schools, the level of public confidence has continued to decline. The US Congress is at the bottom of the list, at 10% of respondents indicating confidence. In 1980, Ronald Reagan was elected president claiming, "Government is not the solution to our problem. Government IS the problem" (Reagan, 1981). Since declaring that the government is the enemy of the people, the Republican Party has stated that the federal government is incapable of managing anything. In some cases, such as the incompetent declaration and management of the Iraq War by the Bush Administration, it became a self-fulfilling prophecy.

One of the more salient results of the counterculture was the burial of the Protestant ethic. No longer was work ennobling; culturally, it became a means to consume. Daniel Bell (1976) opined, "When the Protestant ethic was sundered from bourgeois society, only the hedonism remained, and the capitalist system lost its transcendental ethic" (p. 21). Bell saw the demise of the Protestant ethic as a consequence of the emergence of a system of mass production and mass consumption, instant credit, and the creation of new wants and needs. Certainly, these provided the material undergirding of the cultural revolution. Once the movement was over and the countercultural critique of contemporary capitalism as waste production and consumption had been effaced, the engine of consumer capitalism could be turned on full speed. As long as it increased sales, merchandisers could embrace the countercultural ethic, 'If it feels good, do it,' which was literally turned into a sales slogan, complete with the Nike swoosh. The hedonistic impulses released by the counterculture had lost their oppositional content and were indulged in for their own pleasures, generating the age of narcissism (Lasch, 1978); the 1970s was labeled the 'me decade' (Wolfe, 1976). Americans could indulge in mass therapy, sex, drugs, higher states of consciousness, and rampant commodity consumption without guilt, but always for a price.

Perhaps the greatest impact of the counterculture was on sex roles. Beginning with hippies' gender bending, the counterculture problematized gender roles, especially male gender role expectations. The countercultural emphasis on subjectivity and feelings as new sensibilities, the rebellion of women against sexism, and the gay liberation movement undermined the patriarchy and paternalism that permeated the dominant culture (Freeman, 1975).

In the 1970s and 1980s, glass ceilings were shattered as women advanced in academia, medicine, law, science, politics, and business. However, role expectations for males also escalated. No longer was it sufficient for males to 'bring home the bacon,' but they also had to be loving and supportive members of their families, which for many men was beyond their emotional capabilities (Faludi, 1999; Kimmel, 1996). The rising expectations of women for male role performance, especially in the family, such as sharing household chores, created male anxiety, especially sexual anxiety. To exacerbate male anxiety, economic changes were eliminating working-class jobs, especially those that produced enough income so that the family could depend on a single wage earner. Simultaneously, jobs in the office, which could be held by either males or females, were increasing. If masculinity was defined as earning enough money to support one's family, throughout the late 1970s to the present, fewer and fewer men were able to meet the criterion. In order to make ends meet, wives had to take up jobs in the labor force. This gave them an independent source of income and moved them out of the house, destabilizing male hegemony in the home. Many men bolted, abandoning their families (Ehrenreich, 1983); others were thrown out (Faludi, 1999). The counterculture

influenced the demise of the nuclear family and the rise of gender wars.

In response to feminism and the emergence of a vigorous gay community demanding civil rights for itself, the cultural and political right has reacted by sponsoring cultures of violence (Gibson, 1994). The elections of Ronald Reagan and George W. Bush created cowboy chic fads, with copious pictures of the presidents on their respective ranches. Both political regimes attacked women's health care rights, were antigay, and attempted to resurrect an outmoded image of masculinity that emphasized emotional restraint, outdoorsmanship, familiarity with guns, military glory, and control of violence. The elections of Democrats Bill Clinton and Barack Obama, both with countercultural credentials, resulted in massive purchases of guns and threats of assassination.

Beginning in the 1980s and rising throughout the 1990s to the present, one of the major indicators of the crisis of masculinity has been the emergence of bullying as a serious social issue. Although the literature is unclear as to whether there has been an increase in bullying over time, what has become clear is that much bullying in school is done by more popular students against their less popular peers (Dijkstra et al., 2008; Holt and Espelage, 2007; Pellegrini et al., 2010). Much high school bullying is done by members of the football team and has the tacit approval of administration (Larkin, 2007; Lefkowitz, 1997).

Rampage shootings by marginalized males have escalated throughout the 1980s to the present. They began in schools and workplaces, subsequently spreading to a myriad of public venues, including colleges, shopping malls, movie theaters, government buildings, military bases, and churches (Ames, 2005; Kellner, 2008). An overwhelming number of rampage shooters were bullied, harassed, and intimidated in school or on the job. Rampage shootings were often revenge for the humiliation and emasculation experienced by the shooter (Kimmel and Mahler, 2003).

Between 1993 and 1996, United States experienced a minor social movement that this author identified as "The Revolt of the Angry White Male" (Larkin, 2011), which began as a response against the assault ban contained in the Brady Bill, passed by Congress during the early days of the Clinton administration. This particular period saw a rise in right-wing hate groups, neo-Nazis, skinheads, weekend warriors, paintball war games, paramilitary groups, 'unorganized' militias, and right-wing terrorist groups. The constituency for this movement was marginal males; their prime target was the federal government, which was seen as protecting 'feminazis,' gays, Jews, and people of color (referred to within the movement as 'mud people'). The movement began with a shootout between the Bureau of Alcohol, Tobacco, and Firearms, the Federal Bureau of Investigation, and a white racist named Randy Weaver in Ruby Ridge, Idaho. This was followed by the siege of the Branch Davidian compound in Waco, Texas, in 1993. The siege was revenged by Timothy McVeigh and Terry Nichols in the bombing of the federal building in Oklahoma City. The movement ended with capture of the Montana Freemen in June 1996.

Meantime, the crisis in masculinity generated by the counterculture continues apace. The political and religious right attempt to limit women's access to abortions, attack Planned Parenthood women's health facilities, assassinate abortion-providing doctors, and attempt to restrict access to contraception. The war against homosexuality has been much less successful, although several Southern states have attempted to pass and implement antisodomy laws. Numerous states have been passing gay marriage laws since the Supreme Court ruled that married same-sex couples are entitled the same federal benefits as heterosexual couples and let stand a California State Supreme Court decision allowing gay marriages in that state.

As noted throughout this article, one of the most prominent ideological features of the counterculture was the denigration of functionally rational thought forms, and the substitution of subjectivism as the most valuable way of knowing (Foss, 1972). The rise of subjectivism in a significant portion of American youth had several consequences. First, it opened up American society to the inclusion of non-Western thought forms, including Hindu spiritualism and Buddhist notions of reality, both of which denigrated the material world. Second, it ushered in notions of ecological or holistic thinking, as opposed to the linearity of scientific thought. Critiques of functional rationalism could be found in the works of Phillip Slater (1975) and Theodore Rosack (1973). TenHouten and Kaplan (1973) developed a synthesis of 'propositional' (scientific) and 'appositional' or 'synthetic' modes of thought, suggesting their lateralization in the brain (right brain versus left brain modes of thinking). They also suggested that human knowledge of a higher level of rationality includes both modalities.

The counterculture spread beyond the confines of middle-class youth to practically every sector of society. In the social sciences, young radicals attacked the dominant paradigm of structural functionalism as inherently conservative and unable to properly conceptualize social conflict (Foss, 1963; Mills, 1959). Marxism and neo-Marxism, especially that of the Frankfurt school, which emphasized cultural issues, challenged the structural functionalism that dominated mid-century social sciences. The whole idea of grand theories of how societies work was challenged by the rise of the school of ethnomethodology, which appealed to the subjectivism of young radicals. Ethnomethodology was the study of the methods by which human beings attempted to make meaning from their environment (Mullins, 1973). The rise of competing schools to structural functionalism in the social sciences has led to what Kuhn (1962) referred to as a 'paradigm crisis,' in which several paradigms contest for dominance in the field, but no consensus exists.

In psychology, the subjectivism of countercultural young psychologists gave rise to humanistic psychology that, borrowing from the work of Abraham Maslow (1954, 1962), emphasized the positive aspects of psychological development, rather than focusing on pathology. The rise of humanistic psychology within the profession dramatically expanded the field, giving rise to the 'Human Potentials Movement,' encouraging psychotherapists to focus on psychological 'growth,' rather than deficits. In the late 1960s and early 1970s, there was an explosion of the psychological marketplace as therapists offered group therapy, marathon weekends, sex therapy, and retreats, for example. They appealed to an affluent middle-class clientele that wanted to actualize their inner potential as human beings.

Within academic psychology, the dominant paradigm of behaviorism was overthrown by cognitive psychology (Berlyne, 1975; Greenwood, 1999). In line with the subjectivism of the counterculture, newly emerging psychologists were not going to treat the cognitive functions of human beings as black boxes and only look at operant conditioning and reinforcement schedules in the mode of B.F. Skinner (1938, 1953).

Within the profession, many professionals began to question the 'dark' side of psychology, that is, its role as a mechanism of social control. Chief among these critics were R.D. Laing (1999) and Thomas Szasz (1961, 1965). Laing discussed schizophrenia as a response to a schizophrenogenic, or an insane, environment. The implication of his theory was to treat the environment rather than the patient, whose responses were rational, given the context. Szasz, on the other hand, viewed psychiatry, especially as it intersected the legal realm, as a process of legitimation of social control over people who are otherwise seen as ungovernable. The anti-psychiatry movement of which Laing and Szasz were part, led to the rise of the Mental Patients Liberation Front (Zito, 2005), in particular, and the disability rights movement in general. These movements led to the passage of the Education for All Handicapped Children (PL 94-142) in 1975, and the Americans with Disabilities Act of 1990.

Literally, no academic discipline was untouched by the countercultural revolution. Conventional economics was disrupted by the intrusion of Marxist-oriented political economists. In 1968, the Union of Radical Political Economists was founded at Harvard University and the University of Michigan (Union of Radical Political Economists, n.d.), rising in popularity through the 1970s, and tapering off after that.

Literature studies were influenced by postmodernism, a direct descendant of countercultural sensibilities. Ethnic studies have emerged on major college campuses, including black studies, and Latino studies, in which minority students have been studying the history, sociology, psychology, and literature of their own diaspora. Most importantly, every major field has developed a feminist component. In addition to women's studies on college campuses, there are feminist sociologists, economists, psychologists, anthropologists, and political scientists. Women have increased their enrollments in the hard sciences as well.

Although the counterculture is generally characterized as antitechnological, young radicals, Vietnam War resisters, and technohippies were heavily involved in developing the personal computer in and around the campus of Stanford University (Markoff, 2008). One instrumental group was called the Homebrew Computer Club, established in the 1970s by war resistor, Fred Moore, who thought he could design a personal computer that could make him organize antiwar protests more efficiently.

The more academic institutes were directed at creating artificial intelligence. One was organized by John McCarthy, a card-carrying member of the Communist Party. The other was operated by Doug Englebart; both were heavily involved in countercultural activities. Markoff noted that often times when walking through the labs, one could smell marijuana being smoked. Both Steve Jobs and Steve Wozniak, founders of Apple Computer, were heavily involved in the counterculture. All these people were advocating open sourcing, which expressed the countercultural notion of democratizing technology and wresting it away from large bureaucratic state and corporate institutions.

Countercultures in History

Human societies have experienced cultural revolutions from time immemorial. Exodus in the Bible is a mythological documentation of a cultural revolution whereby Israelites shed their slave mentalities and their worship of graven images. They become Jews, a monotheistic nation worthy of self-governance and management of their land in harmony with nature. However, the counterculture of the 1960s awakened historical scholars' interest in countercultures and cultural revolutions. Therefore, the study of countercultures is relatively new.

Perhaps the best documented historical counterculture is that which existed in England during the revolution between 1640 and 1660. The two decades of the revolution began with the meeting of the Long Parliament, followed by the interregnum between the beheading of Charles I in 1649, and ended with the restoration of Charles II (Hill, 1961). According to historian Christopher Hill (1972):

> There were … two revolutions of mid-seventeenth-century England. The one which succeeded, established the sacred rights of property …, gave political power to the propertied …, and removed all impediments to the triumph of the ideology of the men of property – the Protestant ethic. There was, however, another revolution, which never happened, though, from time to time it threatened. This might have established communal property, a far wider democracy in political and legal institutions, might have disestablished the state church and rejected the Protestant ethic. (p. 15)

The successful cultural revolution championed those values associated with the merchant class and what Max Weber (1958) referred to as 'worldly asceticism': work as the glorification of God, frugality, rationality, and emotional restraint. This value system became predominant during the Industrial Revolution and was important in the transformation of an agrarian population into an industrial workforce. It also gave rise to a new social type: the rational calculator, for whom time is money, capital accumulation is evidence of God's favor, and all decisions are based upon a cost-benefit analysis.

The second cultural revolution was from below and championed an agrarian communism (Hill, 1972). It also emerged from Protestantism, but it was a much different Protestantism than that espoused by the merchant class. It expressed the notion that if all men are created equal, then why should some men have dominion over others? It was the ideology of the 'nonconformist sects' such as Quakers, and secular rebels, such as Ranters, Lollards, Diggers, Levelers, and other dissident groups that demanded a radical egalitarianism. The radicals often met in ale houses were blasphemous, smoked tobacco as a mind altering drug, and offered a vision of an egalitarian society that was described as 'the world turned upside down.'

Conclusion

'The' counterculture of the 1960s and early 1970s emerged out of the middle-class youth movement, which alternated between periods of political and cultural intensification (Foss and Larkin, 1976). The counterculture was self-defined in opposition to the dominant culture, and framed itself as a culture of life opposing the dominant culture of death. Following the social movement period, numerous aspects of the counterculture were divested of their oppositional content and institutionalized into the dominant society. This created a cultural transformation. It opened up employment opportunities for women and minorities, incorporated new thought forms and technologies, transformed academic disciplines, and led to the development of personal computers.

Countercultures are generated by social movements at a point in time when the old culture becomes an impediment to change. The emergence of Protestantism and the Protestant ethic during the English revolution and throughout Europe in the seventeenth century provided legitimacy for a newly emerging capitalist class that took control over a society formerly run by an agrarian aristocracy. Similarly, in the mid-twentieth century, in a society based on high levels of consumption and production, the Protestant ethic no longer made sense. Although resisted by dominant elites when it was a countercultural value, once the Protestant ethic was dead, capital danced its grave, belatedly understanding that the new sensibility could be exploited in a consumer-based economy. However, the counterculture has been responsible for the generation of 'culture wars' in its wake. The use of psychedelics, marijuana, and hard drugs were rigorously opposed in the dominant culture, resulting in the war on drugs. Liberalized views of sexuality were incorporated into advertising copy and used to sell products. Yet, the fight for women's access to abortion and female health care has been a flash point for wedge issues since the 1970s. Similarly, the crisis of masculinity created by the counterculture has been resisted by the cultural right that has denigrated rape, demanded access to firearms for all, sponsored and lionized violent male subcultures, and has resisted the inclusion of gays into mainstream society.

Songs That Represent the Counterculture Ethos of the 1960s

http://www.youtube.com/watch?v=9Ha1eqHDu_w – "Ballad of a Thin Man," by Bob Dylan, 1965. Dylan was considered the poet laureate and visionary of the counterculture. The song satirizes Mr. Jones, a straight person who is trying to understand the counterculture but who cannot make sense of it using conventional means. The message is that the alternate reality can only be subjectively experienced.

http://www.youtube.com/watch?v=P-Q9D4dcYng – "A Day in the Life," by the Beatles, 1967. Reminiscent of Bob Dylan's "Ballad of a Thin Man," it satirizes a man who 'made it' but did not realize 'that the light had changed.' It pokes fun at the competitive struggle and bureaucratic functioning. It takes Dylan a step further by celebrating the psychedelic experience both in musical texture and in lyrics when the Beatles tell the listener that they "would like to turn you on," as the music crescendos to a psychedelic peak.

http://www.youtube.com/watch?v=yRhq-yO1KN8 – "Imagine," by John Lennon, 1971. Written after the Beatles had split up and had declared the end of the movement, John Lennon wrote this tribute to the vision of the counterculture.

http://www.youtube.com/watch?v=26bZZwPs5zM – "Let It Be," by John Lennon and Paul McCartney, 1970. This particular sad song announced both the end of the middle-class youth movement and the breakup of the Beatles. The Beatles, who were seen by many as the troubadours of the movement, told their followers that there was nothing that could be done, and to "let it be."

http://www.youtube.com/watch?v=5-0bqonqooo – "Light My Fire," by the Doors, 1967. The name of the band came from Aldus Huxley's book, *The Doors of Perception* (Harper & Row, New York, 1954), in which he described his experiences on mescaline. "Light My Fire" is the ultimate combination of sex and drug ecstasies, as it crescendos to an orgasmic conclusion, much in the way of Maurice Ravel's "Bolero."

http://vimeo.com/11205275 – "The Times They Are a Changin," by Bob Dylan, 1964. This song literally became the anthem of the youth movement during the Civil Rights phase, combining the issues of racism and social protest.

http://www.youtube.com/watch?v=WANNqr-vcx0 – "White Rabbit," by the San Francisco band, Jefferson Airplane, 1967. Using the metaphor of Alice in Wonderland, ostensibly a children's story, but in reality, a satire of Victorian British politics, the Airplane crafted what came to be an advertisement for psychedelic drugs.

Counterculture: The Classical View

Abstract

Counterculture is a sociopolitical term indicating a point of dissent between dominant or mainstream ideologies and alternative value systems, so creating a collective voice that can be considered a significant minority. This article explores the origins of the 1960s, counterculture in the 1950s Beats, and the emergence of youth cultures. With music recognized as integral to hippie culture, protest, and environmentalism, attention is focused on key artists, global communication, and festivals. Liminal aspects of the counterculture are examined, and the continuing relevance of the term as symbolizing the hegemonic struggles that continue to inform everyday life in societies and cultures worldwide.

While the origins of the term 'counterculture' are unclear, as a key sociopolitical term it is generally accepted as indicating a point of dissent between dominant or mainstream ideologies and alternative value systems that are voiced through, for example, music, art, writing, protest, and lifestyles, so creating a collective voice that can be considered a significant minority. With its origins in the 1950s Beats, the term became an integrative label in the 1960s, where it was interpreted by theorists such as Nuttall (1970), Roszak (1970), and Marcuse (2002) as a 'youth' culture.

Beats

The Beats of the 1940s and 1950s are identified as "the catalysts who precipitated the more widespread social rebellion of the sixties and seventies … kindred spirits determined to practice absolute personal freedom within a society governed by stifling conservative attitudes" (Morgan, 2010: p. 247). Originating in postwar Paris and influenced by the existentionalist values of Jean-Paul Sartre, nihilism, and the futility of action, they were also attracted to Eastern mysticism, poetry, jazz, drugs (marijuana), and literature. In the United States, the influence of Jack Kerouac, dubbed by Turner as "the James Dean of the typewriter" (1996: p. 13) "permeated and shaped an emerging youth culture, not least the themes of its rock culture (from the Beatles, Dylan and the Velvet Underground in the 1960s, to David Bowie, Tom Waits and Patti Smith in the 1970s)." The legacy of Kerouac's "key works – from *On the Road* (1957) to the *Dharma Bums* (1958), *Lonesome Traveller* (1960) to *Desolation Angels* (1965) – are transience, impermanence and the prospect of fresh excitements…" and his theme of "the road is sustained in the machismo legend that surrounds rock as a live medium" (Warner, 2013: p. 30) and the associations of Route 66. Beat poet Allan Ginsberg's legacy lies in his reputation as a campaigner for homosexuality and a libertine whose "signature poem 'Howl!' has been recognized both as 'a premature gay *cri de coeur*' and as a precursor to the 1960s sexual revolution" (Warner, 2013: p. 32). As Warner writes:

> There are various other Beat threads, too, that would feed into the history that follows – from the Buddhist affiliations of Kerouac, Ginsberg and Gary Snyder; interests in the ecology exemplified by Snyder and Michael McClure; the DIY enterprise of publishers of books and journals, characterized most prominently by Lawrence Ferlinghetti and City Lights, but also in the many poetry magazines produced by Leroi Jones, Hettie Jones, Diane di Prima and others, representing entrepreneurial action outside the commercial mainstream; and the black radicalism of Leroi Jones, assuming the name Amiri Barak in 1965, and essentially abandoning his Beat associations for the African-American struggle. (Warner, 2013: p. 33)

In the United Kingdom, the propeace, antiwar refrains of American Beat style resonated with the Campaign for Nuclear Disarmament (CND), which was led by philosopher Bertrand Russell, Canon John Collins, the Labor Party's Michael Foot, novelist J.B. Priestly, and emerging musicians, artists, writers, and poets. Jazz trumpeter and writer Jeff Nuttall provides a perceptive reflection on the CND campaign and the rise of the UK underground (a term used in harness with counterculture) in his book, *Bomb Culture* (1970).

The dialogue between Beat and Counterculture is associated with "Bob Dylan's meeting with Allen Ginsberg at the close of 1963" (Wilentz, 2010: p. 69) and was 'followed by the singer's first meeting with the Beatles in the summer of 1964.' Dylan then brought Ginsberg and the Beatles together in May 1965, "inviting them all to join him in his hotel suite after an Albert Hall gig in London" (Miles, 1990: pp. 369–370). "Thus, within a year and a half, the leading players in an increasingly influential generation of popular musicians would cross existing artistic boundaries to make positive contact with the most dynamic and high profile member of the Beat fraternity" (Warner, 2013: p. 238).

The Emergence of Youth Cultures

Of equal importance to the rise of the counterculture was the identification of the teenager as a precursor to 1960s youth culture. This previously unnamed stage (postchildhood, preadolescent), identified and discussed by sociologists and newspapers alike, was triggered by a new emphasis on attitude – attributable in part to the 1950s advent of rock 'n' roll, coffee bars, the jukebox, and such role models as Elvis Presley and

Buddy Holly, and American movies cultivating images of adolescent life from *Rebel Without A Cause* (1955) to *Rock Around The Clock* (1956). Between 1946 and 1951, a record 22 million babies were born in the United States, giving rise to the phrase baby boomers. Born into an affluent economy, and a growing media technology, they were to be an important part of the emergent youth culture of the 1960s.

The United Kingdom, in the 1950s and 1960s was a society in transition and the emerging teenage culture was, in part, a response to this situation. While there was less spending power for British teenagers than their US counterparts, both experienced an overall rise in the standard of living, which was accompanied by a trend toward personal consumption – fashion, records and record players, cinema and other entertainment, including coffee bar culture. What is significant, in this context, are the specifics of consumption, not least lifestyle and leisure, and by the mid-1960s it seemed that the paralyzing grayness that had characterized British society during the post-war period was replaced, almost overnight, by Carnaby Street color, an underground youth culture, and the Beatles. The identification of underground/counterculture with British youth rests more on cultural politics – arts labs, local underground magazines, legalize pot rallies, free pop concerts, and psychedelic 'head' shops. UFO was headlined as London's answer to Haight Ashbury; the Electric Garden, later renamed Middle Earth, opened in Covent Garden. While there were student protests against the American Embassy in Grosvenor Square (1968) at which Mick Jagger was present, and which led to his personal response in 'Street Fighting Man,' sit-ins at various art colleges, and a continuing protest against war (CND, and such slogans as 'Make Love Not War'), as my colleague, historian Steven Fielding observes, despite the visibility of Tariq Ali and the VSC, the motives of most student protesters were closer to the Beatles sentiments than those of Mick Jagger. Their 1968 song, 'Revolution' spelt it out: 'we all want to change the world. But when you talk about destruction, don't you know that you can count me out'.

1960s Counterculture

Roszak identified "the young (qualified as perhaps only a minority of the university campus population) who find themselves cast as the only effective radical opposition within their societies" (1970: p. 2). He described them as 'technocracy's children' – disaffected middle-class youth who wished to break away from the bourgeois and technocratic world of their parents, and the increasing reliance upon technology and rational-scientific reasoning.

> By way of a dialectic Marx could never have imagined, technocratic America produces a potentially revolutionary element among its own youth. The bourgeoisie, instead of discovering the class enemy in its factories, finds it across the breakfast table in the person of its own pampered children. (1969: p. 34)

Nuttall (1970) also draws attention to the escalating Cold War and the constant threat of a nuclear holocaust. As Bennett notes, 'During the late 1960s, the atrocities of Nazi Germany and the horrific realization of the destructive power of the atomic bomb were disturbing facets of a recent past, while the Cold War and the escalating conflict in Vietnam served as current reminders of the highly pathological aspects of the technocratic society (see Bennett, 2005).

The 1960s counterculture has been identified as a generational youth culture that challenged both the potential disasters inherent in an advancing technology and the traditional concepts of career, education, and morality; and a cultural phenomenon with the potential to create a new cultural sphere beyond and ideologically separated from the parent culture. Evidenced in the United States both in New Left Politics (Students for a Democratic Society) and the Hippies, there is the suggestion of an initial duality – with the former embracing political activism and a concern for health, education, and the environment, and the latter a more bohemian lifestyle and cultural politics. In October 1967, while "flower power wilted, a new movement was born… This was the Youth International Party (Yippies). It was not to hit the headlines until August 1968" (Neville, 1971: p. 30) when their revolutionary strategy moved toward an attack on the establishment through aesthetic politics – mocking militarism, exorcising the Pentagon, throwing money on to the floor of the New York Stock Exchange and nominating a pig for President. "At a deeper level both extremes were united in their attack on the traditional institutions that reproduce dominant cultural–ideological relations – the family, education, media, marriage and the sexual division of labor. There was a shared emphasis on the freedom to question and experiment, a commitment to personal action, and an intensive examination of the self" (Whiteley, 1992: p. 83) whether pathologically invasive or creatively expressive. As Roszak wrote at the time: "Beat-hip bohemianism may be too withdrawn from social action to suit New Left Radicalism; but the withdrawal is a direction the activist can readily understand… We see the underlying unity of the countercultural variety, then, if we see beat-hip bohemianism as an effort to work out the personality and total life style that follow from New Left social criticism" (1970: p. 66).

Hippies

The hippies were a significant aspect of the counterculture and were initially centered on San Francisco's Haight Ashbury district, representing a style of cultural politics and ostensibly rejecting mainstream society. Not least they advocated nonviolence and peace, promoting instead openness and tolerance, seeking spiritual guidance from sources outside the Judeo-Christian tradition, particularly Eastern religions, as well as astrology. Their promotion of recreational drugs, such as marijuana and lysergic acid diethylamide (LSD) was justified as a means of attaining an expanded consciousness. The novelist Ken Kesey was one of the best-known literary spokesmen for the movement, and became famous for the bus tours he made with the so-called Merry Pranksters and his advocacy of LSD. Wolfe (1968) documented the travels of Ken Kesey and his 'Merry Pranksters' during the mid-1960s. Similarly, Thompson's (1993) *Fear and Loathing in Las Vegas* also pays due homage to the countercultural legacy and its vision of a new world.

Folk and rock music were an integral part of hippie culture. In a period of heightened social, political, and psychological

awareness, and rapidly increasing global communications technologies, popular music was recognized as a social force, which expressed issues of cultural and political significance across a wide geographic area. As Jeff Nuttall observed, two of the aims of the Underground were "to release forces into the prevailing culture that would dislocate society, untie its stabilizing knots of morality, punctuality, servility and property; and [to] expand the range of human consciousness outside the continuing and ultimately soul-destroying boundaries of the political utilitarian frame of reference" (1970: p. 249), a philosophy which resonated with the identification of rock as a political weapon. In this respect, John Lennon's 'All You Need is Love' is significant as the world's first live global television linkup. Composed as a 'sing along' for the international television program, 'Our World,' the program was broadcast via satellite on 25 June 1967, and was viewed by an estimated 400 million people in 26 countries throughout the world.

As a collective experience, rock appeared to provide the means whereby young people could explore "the politics of consciousness, love, loneliness, depersonalization the search for the truth of the person, and the attempt to set up an alternative life style" (Roszak, 1970: p. 156). Richard Neville comments, "From Berlin to Berkeley, from Zurich to Notting Hill, Movement members exchange a gut solidarity, sharing common inspirations, strategy, style, mood and vocabulary. Long hair is their declaration of independence, pop music their Esperanto and they puff pot in their peace pipe" (1971: p. 14). It is also relevant to note that the distinction between music for living by, and music for leisure was of fundamental importance to the counterculture, highlighting the ways in which music and sociocultural politics could fuse into a collective experience. As such, the impact of noise (inharmonious sound, distortion, dissonance, and the connotations surrounding discord itself) can be interpreted as underpinning a revolutionary agenda suggestive of a state of creative anarchy (to an extent, this can be traced back to the romantic anarchism of the Beats), which is arguably distinct from the more soft-focus connotations of 'All You Need is Love' (The Beatles, 1968) and the pacifist agenda implicit in such slogans as 'Make Love Not War.' Although it is recognized that the fight against middle-class prurience led increasingly toward an explicit identification of sexual freedom with total freedom which, at its extreme, embraced pornography, including the so-termed velvet underground advertisements for blue moves and classified ads, and *play power*'s "Female Fuckability Test" (Neville, 1971: p. 14). As such, while love was fundamental to the philosophy of the counterculture, there was nevertheless a marked difference between the transcendental spirituality promised to followers of the Maharishi Mahesh Yogi and the revolutionary liberation of the Yippie Party's Jerry Rubin and his symbolic call for patricide. If, however, Roszak is correct in identifying "beat-hip bohemianism as an effort to work out the personality and total life style that follow from New Left social criticism" (1970: p. 66), then a movement toward a communality based on love could appear a logical development. Discord and the darker extremes of 'noise' thus come into focus as the first stage in the countercultural agenda of establishing a relevant and alternative lifestyle.

An extreme example comes from the MC5, Detroit's leading underground band, who performed at revolutionary rallies against a political backdrop of racial inequality and suppression, most notably the 1967 riots when confrontations with the US national guard and US army troops resulted in 43 deaths and over 7000 arrests. Managed by John Sinclair, 'Minister of Information' for the White Panthers, the band's second single, 'Looking at You' was supposedly recorded in downtown Detroit "sometime circa the 1967 riots, feeding the myth that the band were a group of 'rock and roll guerrillas' who both fomented and embodied disorder with their rousing performances" (Waksman, 1998: p. 47) and feedback-laden sound. Further violence against protesters at the 1968 Democratic National Convention was highlighted by MC5s revolutionary rallying cry, 'Kick Out the Jams, Motherfuckers.' As Jim Deregotis writes, "Strange as it seems in retrospect, the music industry thought revolution might be the next big marketing concept circa the late '60s, and MC5 were signed to Elektra (along with their younger 'baby brother' band, the Stooges) by Danny Field (A&R) who later managed The Ramones." Jim Deregotis, The 'MC5 Classic still has plenty of kick to it,' Great Albums: The MC5, Kick Out the Jams' 11 August 2002 http://www.jimdero.com/News2001/GreatAug4MC5.htm http://www.rollingstone.com/music/albumreviews/kick-out-the-jams-19690405 accessed 14.04.11.

The Beatles also offered a vision of chaos in the Coda to 'A Day In the Life' (*Sgt. Pepper's Lonely Hearts Club Band*, 1967) where a spiraling ascent of sound challenges "the warm combination of acoustic guitar and piano" (Hannan, 2008: p. 59) that introduces the song, the complacency inherent in contemporary society ('A crowd of stood and stared…,' 'a crowd of people turned away'). The dramatic effect of the indeterminate textures of the ascending orchestral clusters is contextually anarchic in its intrusion into the passacaglia-like countermelody of the first two verses, albeit that Lennon's lyrical vocal "features an unusually expressive use of nonharmonic tones, notably the leaps to dissonant notes in the latter part of the first and fourth bars ('I read the news to-day/oh-boy-/a-about a luck-y man who/made the grade'), so hinting at an underlying disillusionment" (O'Grady, 1983: p. 137). McCartney's second section is more frantic in its delivery, coming to an abrupt and fuzzy conclusion at the words "Somebody spoke and I went into a dream," the vocal line becoming obscured by the progressively louder orchestral unisons on the root of each chord, before a two-bar unison brass motif plunges the key down a minor third for the return of the first section. This time, the bass leads to the intense orchestral build up before the shifting timbres of the final sustained piano chord and its 30-s decay lead finally into "a noisy 15 kHz tone leads to a 2-s piece of gibberish which was cut into the run-out groove of the L.P" (Hannan, 2008: p. 61), so casting doubt as to whether the song's powerful imagery and disruptive musical aesthetics would inspire listeners to wake up and question (as suggested by the ringing alarm clock that heralds McCartney's middle section and the crowing cock in 'Good Morning, Good Morning' or whether it would be interpreted as yet another example of the Beatles' love of the "slicks and tricks of production" (Goldstein, 1967: p. 173). Russell Reising and Jim LeBlanc note that psychedelic rock has used alarm clocks, chimes, bells, the effects of clocks ticking, and other effects to signal psychedelic awakening. "Within and without: *Sgt. Pepper's Lonely Hearts Club Band* and Psychedelic Insight" in Julien (2008: p. 111). It is also reported that

McCartney's interest in the avant-garde, and his admiration for Stockhausen, led to the inclusion of an "instrumental passage… [with] a spiraling ascent of sound… [starting] the passage with all instruments on their lowest note and climbing to the highest in their own time" (Martin and Pearson, 1994: p. 56). (see Whiteley, 2013: for a full discussion of the Beatles and 'A Day in the Life' and the MC5 and 'Kick Out the Jams.')

It is also suggested that songs associated with the counterculture – "through their musical style, their mode of performance, use and interpretation – point towards particular historical moments, knots of collective experience, cultural traditions and so forth. At this level – the level of style-indicators and cultural codes – music can be taken to represent to us the features of a specific conjuncture (neo-Gramscianism), structure of feeling (Raymond Williams), or chronotope (Bakhtin)" (Middleton, 2000: p. 231) and in previous work (Whiteley, 1992) it was suggested that "drug-related experience works through anaphonic musical signs (i.e., signs that work through structural analogy with non-musical experiences of time, space, movement etc), culturally mediated semiotic coding musical features that work through comparison with other, familiar effects in different styles; intra-cultural interpretation (what countercultural listeners said, cultural resonance (analogy between aspects of the music and of the cultural context); technological innovation" (Middleton, 2000: p. 231). While examples can be drawn from, for example, the Grateful Dead, the Beatles, Pink Floyd, the Doors and the Rolling Stones, its most striking focus can be found in the musical and performing body of Jimi Hendrix, where there are intersecting discourses not only of 'progressiveness' and 'psychedelia,' but also of race, gender, and sexuality. Significant examples would include 'Purple Haze,' 'Love or Confusion,' 'Are You Experienced,' and 'Spanish Castle Magic' (Whiteley, 2000: pp. 235–261).

The hippie's identification with the metaphysical is explored in Lennon's 'Tomorrow Never Knows' (The Beatles, *Revolver*, 1966), which set the agenda for psychedelic music in its evocation of the Vedic teaching 'Be Here Now' – living in the present but conscious of both past and future. Rather than the more usual, extravagant colors of psychedelia, the colliding musical circles are introspective, a sensory experience of Timothy Leary's voluntary ego-death. Leary's *The Psychedelic Experience* (Leary et al., 1964) is a paraphrase of *The Tibetan Book of the Dead* which had influenced Lennon's personal experience of LSD and his composition, 'Tomorrow Never Knows.' This is achieved by looped effects which constantly move to the 'eternal' presence of the tonic (an orchestral chord on Bb major; a Mellotron played on flute setting; another Mellotron oscillating in 6/8 over the 4/4 pulse of the melody line, moving from Bb (the flattened 7th) to C (the tonic on its string setting), so suggesting a musical metaphor for the tug between the conscious/unconscious of psychedelic experience (Whiteley, 2002: p. 219). George Harrison's 'Within You Without You' (*Sgt Pepper's Lonely Heart's Club Band*, 1967) also reflects his search for Eastern mysticism. As George Martin reports, "What appealed to George was the sound – the unique sound the instruments made when used in this very ancient (Indian classical) tradition" (Martin and Pearson, 1994: p. 126). Encapsulated by an endless drone and metric shift between fours, fives, and threes, "the vocal line is doubled by two dilrubas (the dilruba is a bowed lute with a buzzy, nasal, hollow-sounding timbre) and, at certain points, by a (Western) string ensemble (eight violins and three cellos) and, at other points, sitar"… "Harrison's vocal sound is mantra-like, sitting in the back of the mix, dominated by the elaborate tabla playing" (Hannan, 2008: pp. 54–55).

While the search for expanded consciousness through both hallucinogenic drugs and the metaphysical of Eastern religions were important aspects of music associated with the hippie counterculture, "the lyrical content of popular music also took on increasingly radical dimensions as the 1960s progressed. Songwriters and lyricists saw it as their artistic responsibility to respond directly to current social and political issues which, during the mid-1960s, were becoming increasingly more turbulent" (Bennett, 2004: p. xv). These included protests against the war in Vietnam, including The Doors 'The Unknown Soldier,' where the promotional film showed singer Jim Morrison being blindfolded and shot, a scene intended to parody the 'summary executions of untried opponents' featured in US media reports about the Vietnam War (Snowman, 1984: p. 163). The anti-Vietnam War protest was supported by many musicians including John Lennon and his wife Yoko Ono, who staged a 10-day bed-in at the Queen Elizabeth Hotel in Montreal, Canada, in the cause of world peace. 'Give Peace A Chance' was written by Lennon, and recorded live in two sessions in the hotel bedroom.

Festivals

Festivals were an important medium for spreading countercultural ideology. The open-air 'Be-In,' Golden Gate Park, San Francisco, which attracted 20 000 people and featured such pioneering acid-rock groups as Country Joe and the Fish, Moby Grape, the Quicksilver Messenger Service, the Steve Miller Band, Jefferson Airplane and the Grateful dead. "An overawed *Time Magazine* recorded, 'The huge crowd was peaceful … an amazing tribute to Haight-Ashbury.' More accurately it was a tribute to LSD and marijuana, which had been distributed by a dazed Santa Claus" (Neville, 1971: p. 28). The scale and coverage of the Monterey Festival of June 1967 made it an event of supreme importance to the rock world. American acts on the bill included the Byrds, the Paul Butterfield Band, the Grateful Dead, the Blues Project, the Mothers of Invention, Simon and Garfunkel, and the Doors.

Woodstock is recognized as the most important festival of the period, attracting between 400 000 and 500 000 people. It is remembered both for its 'bringing together' of the countercultural generation and its music, which was both politically subversive while acting as a springboard for the more commercial rock and pop events that followed. Country Joe McDonald's "I-Feel-like-I'm-Fixin'-to-Die-Rag" was a direct criticism of the Vietnam War and its sing-along chorus was made world-famous through its inclusion in Michael Wadleigh's film *Woodstock (Three Days of Peace and Love)* (1970). Joni Mitchells 'Woodstock,' dedicated to the Woodstock festival, contains a reference to bombers turning into Butterflies, the bombers in question being those attacking North Vietnamese targets (Bennett, 2004: p. xvi). It was, however, Hendrix's performance of 'The Star Spangled Banner'

that provides the most compelling example of rock as a political weapon. Even though the words are not sung, they were familiar to his audience, and the feedback and sustain provide a commentary on the flag itself as, at the words, 'broad stripes and bright stars,' the sounds plummet and waiver. The attack comes at the evocative 'rocket's red glare' where Hendrix creates the sound of a fighter plane "coming out of a deep dive, the impact of bombs striking the earth and the cries of the Cambodian peasants" (Henderson, 1990: p. 245). The straight melody finally comes through on 'gave proof through the night' and the anthem ends to the sounds of feedback and sustain and a final ear-shattering grind as the guitar strings are treated to a crude bottleneck slide against the mike stand (Whiteley, 2004: p. 25). As Charles Shaar-Murray writes: "the ironies were murderous: a black man with a white guitar; a massive almost white audience wallowing in a paddy field of its own making; the clear, pure, trumpetlike sounds of the familiar melody struggling to pierce through clouds of tear-gas, the explosions of cluster-bombs, the screams of the dying, the crackle of flames, the heavy palls of smoke stinking with human grease, the hovering chatter of helicopters" (1989: p. 24) (see Whiteley, 2004: pp. 18–28). Jimi Hendrix, together with Richie Haven and Sly Stone were the only Afro-American artists to appear at the Woodstock, which has been identified as both the "defining moment of the late 1960s and the swansong of the countercultural movement that characterized the era" (Bennett, 2004: p. xviii).

If Woodstock is largely described as utopian, then the Rolling Stones free concert at Altamont heralded the end of the Age of Aquarius. It also raises the question "of the relationship between performer/audience, the performance, and the musical text itself; that the unmitigated violence at Altamont suggests that for many the songs were interpreted as inciting brutality, that they provided a model for behavioral patterns" (Whiteley, 1997: pp. 84–85). While most agree that the reason for the violence at Altamont – which began well before the Stones took the stage – had more to do with the hiring of Hells Angels as security, few would argue that the menacing subject matter and sound of songs like 'Sympathy for the Devil' and 'Midnight Rambler' would "hardly calm the already explosive atmosphere" (1997: p. 84). The Maysles Brothers film of the concert, *Gimme Shelter* (1971) provides a disturbing insight into those attending Altamont: one murdered, total dead four, two run over, one drowned in a drainage ditch, hundreds injured, and countless more stoned on acid.

Altamont was only one of a series of crisis, which signaled the end of the 1960s counterculture. The association of LSD with Satanism which had resulted in the murders of Sharon Tate and four of her friends by members of the Manson 'family' led to a panic reaction to the adverse effects of drugs. Publicity surrounding the death of famous rock stars also led to highly volatile criticisms of the counterculture and in particular the concept of creativity through drug experience. In September 1970, Hendrix had been found dead from inhalation of vomit following barbiturate intoxication. On 4 October of the same year, Janis Joplin died from a heroin overdose. In 1971, Jim Morrison died of a heart attack caused by heroin or alcohol in Paris. Personal survival seemed paramount and the US broadcast license authorities warned radio stations that they would be subverting the government's campaign against drug abuse if they played lyrics, which mentioned dope. Finally, the shooting of four students at Kent State University tragically proved how deep was the gulf between those who wanted to change America and its policies in Vietnam, and the conservative majority who believed in law and order above everything else.

Countercultures: The Broader Picture

While academic attention has been focused largely on the United States and the United Kingdom, the hippie movement quickly established a presence throughout the Western World, with countercultural movements emerging in, for example, Christiania (Denmark) (see Hall, 2014), Naples (Italy) (see Vacca, 2013: pp. 67–84), East and West Berlin (Germany) (see Stahl, 2014), and in some areas of South America, Asia, and the former Soviet bloc. In Paris, university students and workers joined forces to protest about workers' right and the conditions in factories, while across Europe students occupied universities and demonstrated for better facilities. Although activists received considerable attention, as Joel Fort observed, "they probably number no more than tens of thousands in such groups as the Students for a Democratic Society, antiwar and antidraft groups, student power advocates and some elements of the hippies and yippies. There are the equally radical groups of special minorities, namely the Black Panthers, Brown Berets, and others seeking power, dignity and sometimes justice for racial and cultural minorities" (1969: p. 210).

In the United States, attention focused on Civil Rights. "In October 1966 the Student Nonviolent Coordinating Committee (SNC) was established to enable students to become organized in the battle for civil rights. However, neither the SNCC nor President Kennedy's Civil Rights Bill, passed in 1964, served to alleviate the abject poverty and total political impotence of African Americans. Increasing racial discrimination and harassment across the US led to inner-city riots…[as] Civil rights organizations were superseded by the Black Power movement under the leadership of Stokely Carmichael" (Bennett, 2004: p. xvii). Civil Rights activist, Martin Luther King was best known for his advocacy of nonviolent civil disobedience and his stirring speech 'I have a dream.' He was assassinated on 4 April 1968. Malcolm X, the human rights activist was assassinated on 21 April 1965. His father had earlier been murdered by the Klu Klux Klan. Black artists associated with the Black Power movement included James Brown, 'Say It Loud: I'm Black and I'm Proud,' and Aretha Franklin, 'Respect.'

It is also interesting to note the emergence of the so-called Jesus hippies, commonly dubbed 'Jesus freaks.' Questioning "the authority of the church and reinstating biblical authority, most commonly apocalyptic, they simultaneously retained what was widely considered a countercultural aesthetic, often sporting the hippie image while using popular music for Christian proselytizing." As Young observes, "Barry McGuire's classic 'Eve of Destruction' (1965) gained notoriety within the context of radicals, revolutionaries, and those who were convinced the world was on the brink of either cosmic or physical annihilation. Along with Bob Dylan, McGuire's conversion to Christianity gave credibility to the rising Jesus-freak revolution. As celebrities such as Johnny Cash and Eric Clapton converted, revivalistic

Christianity found entry into the entertainment industry, launching a groundswell of activity … Fleetwood Mac's Jeremy Spencer joined the rigid and controversial commune the Children of God, a notable doomsday group. Secular rock groups also explored religious themes, adding to the already enigmatic culture of Christian hippies. These included The Byrds' version of 'Jesus is Just Alright' (1969), Ocean's 'Put Your Hand in the Hand' (1970), Creedence Clearwater Revival's 'Bad Moon Rising' (1969), and Norman Greenbaum's 'Spirit In The Sky' (1969) (see Young, 2013: pp. 51–67).

Despite the breadth of the countercultural movement, research suggests that women were largely marginalized. As Roszak observed, the struggle for liberation was seen mainly "as the province of men who must prove themselves by 'laying their balls on the line'. Too often this suggests that the female of the species must content herself with keeping the home fires burning for her battle-scarred champion or joining the struggle as a camp follower. In either case, the community is saved *for* her, not *by* her" (1970: footnote to p. 65). Despite the emergence of the so-termed women's liberation movement and the questioning of power relations in personal life (in reproduction, sexual relationships, the household division of labor, popular culture, why certain ethnic minorities and working class women were marginalized in their access to the production and consumption of knowledge and culture, and why women generally were not represented within the hierarchies of science and arts) the counterculture remained male-dominated. The breaking down of old-restraints ('free love') privileged a male sexuality, confirming the traditional definitions of masculinity and femininity under the dubious banner of progressiveness, and in the field of music there was little real opportunity to either take control or enjoy the prestige offered to male artists. Apart from the biting social and political commentaries from such performers as Joan Baez and Buffy St Marie and the significance of such frontline artists as Mama Cass (The Mamas and the Papas), Grace Slick (Jefferson Airplane), and Janis Joplin (albeit at a cost, with Joplin dying in 1970 and Cass Elliott in 1974) the musical ethos of the period undermined the role of women, positioning them as desexualized earth mothers, fantasy figures, and easy lays. (Whiteley, 2000: pp. 1–94)

It is thus suggested that while there were highly political elements within the counterculture, the movement was not uniformly politicized in a way that dictated that the only way forward was to overthrow the capitalist system by whatever means. Feminist academics identified patriarchy as the major obstacle in achieving personal freedom, and attitudes toward gay and lesbian artists remained problematic, despite the United Kingdom's Homosexual Reform Bill (1967), the promotion of camp taste and drag culture at Andy Warhol's New York Factory, and the Velvet Underground's uncompromising insights into urban culture, sexuality and voyeurism in the *Velvet Underground and Nico*. Warhol's Factory also provided a refuge for drag queens who are celebrated in *The Philosophy of Andy Warhol* (1975), thus providing a crucial link with the 27 June 1969 police raid on the Stonewall Inn gay bar on Christopher Street in Greenwich Village, and the subsequent riots that were the flashpoint of the American gay liberation movement of the 1970s.

In retrospect, it is apparent that the 1960s counterculture incorporated diverse groupings, including student protest, peace and antiwar movements, the civil rights movement, environmentalists, the utopian, dystopian, apocalyptic, and freaks these are discussed in Whiteley and Sklowers edited text on Countercultures and Popular Music (2013), and could also "manifest itself differently at specific times and within specific places depending on local socio-economic, cultural and demographic circumstances" (Bennett, 2013: pp. 19–31). More recently, the term counterculture has come to symbolize 'forms of social action and/or alternative lifestyles and belief that appear – or can be made to appear – to link with the aesthetic, political and cultural trends associated with the late 1960s manifestation of counterculture', so providing a sociocultural-political analogy for the 'hegemonic struggles that continue to inform everyday life in myriad societies and cultures across the globe' (Bennett, 2013).

Counterfactual Reasoning, Qualitative: Philosophical Aspects

Stathis Psillos, University of Athens, Athens, Greece

This article is a revision of the previous edition article by A. Hájek, volume 4, pp. 2872–2874, © 2001, Elsevier Ltd.

Abstract

This article reviews the two major approaches to counterfactual conditionals: the metalinguistic or 'support' approach and the possible worlds approach. It identifies the major problems they face and explores the thought that the core idea behind counterfactual reasoning is to assert that there are not good inductive reasons to affirm simultaneously a generalization and the physical possibility of an exception to it. It also examines the role of counterfactuals in causal inference, causation, and laws of nature.

Subjunctive conditionals or counterfactual conditionals are probably as old as language itself since they give speakers the means to talk about what would or might happen or have happened if certain things were to happen or had happened. In ordinary language, they have the form:

If *x* were (not) the case, then *y* would (not) be the case,
or
If *x* had (not) been the case, then *y* would (not) have been the case.

Subjunctive conditionals leave open the possibility of the realization of whatever is expressed in the antecedent, for example, if John were to come to the party, Mary would not go. Counterfactual (or 'contrary-to-fact') conditionals are such that the antecedent is false; the state-of-affairs expressed in it has not actually obtained, for example, if John had gone to the party, Mary would not have gone. (Here it is an implicit assumption that the actual course of events is that John did *not* go to the party.) Both kinds of conditional contrast to indicative conditionals of the form: *if x is the case, then y is the case*. Although there are differences between them, we will not be detained by them, and instead concentrate on counterfactual conditionals. (From now on, we will follow customary usage and use $\Box\!\rightarrow$ to express the counterfactual 'if…, then…'.)

Counterfactuals fail a number of principles that indicative conditionals satisfy. Most important, they are nonmonotonic, that is they fail the principle of strengthening of the antecedent:

$$X\Box\!\rightarrow Y \text{ does not entail } X\&Z\Box\!\rightarrow Y.$$

Example: If John had been poisoned, he would have died. This does not entail: if John had been poisoned and taken an antidote, he would have died.

Transitivity:

$$X\Box\!\rightarrow Y \text{ and } Y\Box\!\rightarrow Z \text{ does not entail } X\Box\!\rightarrow Z.$$

Example: If John had gone to the market, he would have taken the bus; if John had taken the bus, then he would have gone to his office. These two do not entail: if John had gone to the market, then he would have gone to his office.

Contraposition:

$$X\Box\!\rightarrow Y \text{ does not entail not} - Y\Box\!\rightarrow \text{not} - X.$$

Example: If John had lived in a Euro-zone country, he would have used Euros. This is not equivalent to: If John had not used Euros, he would not have lived in a Euro-zone country.

If we assume that classical semantics apply to indicative conditionals (the indicative conditional is true if either the antecedent is false or the consequent is true), trying to apply classical semantics to counterfactuals leads to their trivialization: Given the actual falsity of the antecedent of a counterfactual, both the counterfactual with the actual consequent and the counterfactual with the negation of the actual consequent end up being true.

Example: Given that the vase was not struck with a hammer, both of the following two conditionals (treated as material conditionals) are true:

If this vase had been struck with a hammer, it would have broken, and
If this vase had been struck with the hammer, it would not have broken.

The failure of the three principles and this unwanted consequence is a *reduction* of the view that classical semantics applies to counterfactuals. But then, what is the right semantics for counterfactuals? What are the truth-conditions of a counterfactual conditional? Or, at least, what are their assertibility conditions? This problem came under sharp focus in the 1940s, when philosophers started to realize that the concept of counterfactual conditionals is instrumental for the explication and understanding of a number of other philosophical concepts. As Nelson Goodman put it in one of the first papers to deal with this issue, "(…) if we lack the means of interpreting counterfactual conditionals, we can hardly claim to have any adequate philosophy of science" (1947: p. 113).

Note that in assessing a counterfactual assertion $X\Box\!\rightarrow Y$, we should replace, as it were, the actual nonoccurrence of X with the supposition that X has occurred. But given that the laws of nature and the actual course of events led to non-X, in supposing the actual occurrence of X, we need to make counterfactual suppositions concerning either the laws or the actual course of events, such that X actually occurred. In particular, we have to assume that either some laws were broken (so that X did happen after all) or that some actual particular matters of fact did not occur. Hence, in specifying the semantics of counterfactuals, we have to take into account considerations concerning the laws of nature and other particular matters of fact prior to the conditions specified in the antecedent of the counterfactuals.

There are two major views concerning the semantics of counterfactuals, the first being introduced by Goodman himself, whereas the second was developed by Robert Stalnaker

and David Lewis (but introduced by William Todd in 1964). Let us examine them in turn.

The Metalinguistic or 'Support' View

On the first major view, known as 'support view' or 'metalinguistic view,' a counterfactual conditional $X\Box\rightarrow Y$ is an elliptic or telescoped argument (or a linguistic construction *about* an argument) such that the antecedent X (taken in its indicative form) together with suitable auxiliary premises entail the consequent (taken in its indicative form). Hence, $X\Box\rightarrow Y$ should not be taken to be a statement at all; its assertoric content is captured by the following argument type:

X&S&L (materially) imply Y,

where L are statements capturing laws of nature and S are singular statements capturing background or collateral conditions that should be 'cotenable' with the antecedent X and express necessary conditions for the consequent to follow.

Example: If this match had been struck (X), it would have lit (Y). For a struck match to light, it is necessary that the match is well made; that it is dry; that there is oxygen; and so on. But these conditions (collectively designated by S) are not sufficient for the lighting of the match; various laws are required (collectively designated by L). Hence, in asserting the counterfactual 'if this match had been struck, it would have lit,' we are committed to the truth of the various statements that describe the laws and the relevant background conditions.

The first general problem with this view concerns the characterization of the relevance relation when it comes to the background–collateral conditions. It cannot be too permissive. If we allowed all true statements to be relevant to the argument, the falsity of the antecedent X (which is *actually* false) would be relevant, too; however, the counterfactual then would be trivially true. It cannot be too restrictive either. The consequent of the counterfactual is false as well. Hence, not-Y is the case. It is not hard to see that given (X&S&L→Y) and not-Y and L, it follows (by obvious steps) that X→not-S. (Assuming, for simplicity that S is 'the match is dry,' the conclusion would be as follows: If the match is struck, it will not be dry!) The point then is that only those background or collateral conditions that are 'cotenable' with the antecedent should be admitted. But which are they? Those conditions S, which are such that if X had been true, S would have been true, too. This is a counterfactual assertion and Goodman thought that this kind of circularity impairs the metalinguistic analysis of counterfactuals.

The second general problem with this view concerns the characterization of laws, which are indispensable for the *connection* between the antecedent and the consequent of a counterfactual. The key thought here is that some generalizations, although true, are unable to 'support' counterfactuals because they are accidental. *Example*: Compare the following two counterfactuals:

A. If x had been a golden sphere, its diameter would not have been more than one mile long.
B. If x had been a plutonium sphere, its diameter would not have been more than one mile long.

(A) is false, while (B) is true – we rightly suppose. And this is because there is a law of nature backing up (B), while the generalization related to (A) is merely accidental (intuitively: if we have had enough gold, we could build a sphere of it with the required diameter; not so with plutonium). So the general statements L that are part of the premises of the argument whose telescopic form is $X\Box\rightarrow Y$ must express *laws of nature* and not merely accidentally true generalizations. But how exactly are we to distinguish between laws and accidents? If we felt that laws are those generalizations that support counterfactuals, whereas accidents are those that do not (see the previous example), then we would move in a(nother) circle. So there is a need to look for ways to distinguish between laws and accidents that do not rely (in the first instance, at least) on their modal force (at least when expressed in their support of counterfactuals). When Goodman brought this problem to the attention of philosophers, the prevailing view of laws was that they are simply regularities (cf Chisholm, 1946); hence, the distinction between laws and accidents (which are regularities too) was taken to be mostly an 'honorific' distinction that is captured by the different epistemic attitudes we have toward them. For instance, laws are those regularities that are projected to the future or that are confirmable by their instances. Sellars (1956: p. 268), however, pointed out that even if laws are taken to be regularities, they are those regularities that are characterized by 'neck-sticking-out-ness,' where this characteristic is captured in the subjunctive mood: 'If this were an A-situation, it would be accompanied by a B-situation.' The counterfactual content of a law then is seen as a 'contextual implication' of a law-statement.

This idea of 'contextual implication' is captured by the supposition view of counterfactuals, which is akin to (although interestingly different from) the metalinguistic view, as this was developed by John Mackie (1973). According to this view, to assert something like $X\Box\rightarrow Y$ is to assert Y *within the scope of the supposition that X*. In other words, we suppose X and then we envisage various possibilities and consequences. This account brings to light the contextuality of counterfactual conditionals, which is not resolvable without some degree of arbitrariness: X did not happen; supposing that X did happen, what else do we have to assume or suppose? What features of the background (including laws and particular matters of fact) should we retain or change? There is no uniquely determined answer to this question, although contextual matters (including a fuller specification of the antecedent of the conditional) might (and as a rule do) help us. *Example*: Is the counterfactual: 'If I had let go of this stone, it would have fallen to the ground' true or false (or assertible or not assertible)? It depends on the context. There are certain conversational contexts in which it would be false to assert it, for example, if this were a precious stone and the owner was very careful with it, so if the stone were to be let go, she would have caught it in midair. *Another example*: Consider the following pair of counterfactuals: 'If Julius Caesar had been in charge of United Nations Forces during the Korean War, then he would have used nuclear weapons' and 'If Julius Caesar had been in charge of United Nations Forces during the Korean War, then he would have used catapults.' Only contextual assumptions can tell us which one, if any, and in what context, is true (or assertible).

The supposition view takes it that counterfactuals are *not* truths about possible words but are ways to express an attitude

toward a possible state of affairs made within the scope of a supposition. The cotenability problem is solved by a legitimate weakening of the cotenability condition: The cotenable premises are taken to be those that are *thought* to be cotenable in a certain conversational context. But how, within this view, can it be explained that laws support counterfactuals while accidents do not? The difference is not in the content of a statement expressing a causal law as opposed to the content of an accidentally true generalization. Rather, the difference is in the circumstances under which it is legitimate (or acceptable) to combine the supposition that X is the case (i.e., the antecedent of the counterfactual $X\Box\rightarrow Y$) with the law L as premises of the relevant argument whose conclusion is Y. Suppose that the sole ground for believing the law L (e.g., All Fs are G) is an enumeration of *all* actual instances (Fai&Gai) of L. Then adding the supposition X, that is, that a *further* a is F, removes the ground for accepting L. We can no longer draw the conclusion that this further a is G. Hence, we cannot assert the counterfactual $X\Box\rightarrow Y$. More generally, if the reasons for accepting L survive placing L within the scope of *the supposition that there are further instances of the law's subject term*, then we can say that the law supports the relevant counterfactual conditional. According to Mackie, the required reasons are ordinary inductive reasons, that is, good inductive evidence for the law. Good inductive evidence, in other words, is evidence for the 'neck-sticking-out-ness' of the law. As Mackie (1974: p. 203) noted, the evidence plays a *double role*. It first establishes inductively a generalization. But then, "it continues to operate separately in making it reasonable to assert the counterfactual conditionals which look like an extension of the law into merely possible worlds" (Mackie 1974).

An interesting related thought comes from Julius Weinberg (1951) who claimed the following: A counterfactual $X\Box\rightarrow Y$ is not best seen as the indicative statement (the statement of a generalization) $X \rightarrow Y$ plus some further antecedent conditions (including that X did not actually happen), but rather as asserting something about the evidence there is for $X\rightarrow Y$, that is, that there is evidence for, and no evidence against, the gereralization: for all X $(X\rightarrow Y)$. Hence, the additional strength a counterfactual is supposed to have over the corresponding generalization is captured by the evidence there is for the generalization.

The Possible Worlds View

Taking literally the view that counterfactuals are used in contemplating *possibilities*, the second major view of the semantics of counterfactuals appeals to possible worlds. In first suggesting this view, Todd (1964: p. 107) noted that when we allow for the possibility that the antecedent of a counterfactual be true, we are "hypothetically substituting a different world for the actual one." On this view, the core meaning of a counterfactual $X\Box\rightarrow Y$ is (roughly): In the possible (but not actual) world where X, Y too.

A possible world is a way the world might be or might have been. For instance, it is possible that gold is not yellow, or that planets describe circular orbits, or that birds do not fly, or that beer does not need yeast to brew. But are there really possible worlds? There are three views here. The *first* is that talk of possible worlds is a mere *facon de parler*, although useful when it comes to assessing counterfactuals (cf Mackie, 1974: p. 199). (I take it that an extension of this view is that possible worlds are useful *fictions*.) The *second* is 'extreme realism,' according to which the way the world *actually* is, is one among the many ways the world could be; hence, the actual world is one among the many possible worlds, the latter being no less real than the actual. The chief advocate of this view was David Lewis (1973). The *third* view is 'abstract realism,' according to which possible worlds are maximally consistent sets of propositions: total ways things might be. A 'possible world' then is fit to represent a concrete reality, but only one of them actually represents anything, that is, the actual world (cf Bennett, 2003).

Stalnaker (1968) developed the core meaning of counterfactuals as follows:

Consider a possible world W in which X is true but otherwise is similar to the actual world @. $X\Box\rightarrow Y$ is true if Y is true in W.

The similarity relation among worlds (a selection function, as Stalnaker put it) is an ordering of possible worlds with respect to their resemblance to the actual world.

Calling an X-world a possible world in which X hold, counterfactuals might be taken to be strict conditionals of the following form:

$X\Box\rightarrow Y$ is true in a world W if Y is true in all X-worlds such-that _____

where the blank is filled by a general condition that X-words should satisfy. Hence, whatever goes into the blank _____ places a restriction on the admissible (or accessible) possible worlds. This idea would model counterfactuals along the lines of strict conditionals of the form:

it is physically necessary that _____
or
it is logically necessary that _____

where the first restriction is to all worlds with the same laws as the actual, whereas the second 'restriction' would be to all possible worlds *simpliciter*.

But this analysis cannot be correct. There is no set of possible worlds W such that $X\rightarrow Y$ throughout W (this is another way to state the fact that counterfactuals are non-monotonic). So Lewis (1973) suggested that counterfactuals $X\Box\rightarrow Y$ are *variably strict conditionals*: each of them is a strict conditional, that is, every X-world *of a certain sort* is a Y-world, but the relevant set of worlds varies with different conditionals.

Like Stalnaker, Lewis took it that worlds are ordered in terms of similarity, or closeness to the actual world. According to this *primitive* notion of 'comparative overall similarity': "we may say that one world is closer to actuality than another if the first resembles our actual world more than the second does, taking account of all the respects of similarity and difference and balancing them off against one another" (1986: p. 163).

But unlike Stalnaker, Lewis took it that in assessing the counterfactual $X\Box\rightarrow Y$, it does not make good sense to talk about *the* closest-to-actual possible X-world. It is not just that there might be more than one closest-to-the actual possible worlds. It is mainly that there might not be even one rightly

deemed *the* closest (even in a limiting sense). Hence, according to Lewis's view:

$X \Box\!\!\rightarrow Y$ is true at a world W if some (accessible) X-world in which Y holds is closer to W than any X-worlds that Y does not hold.

For instance, take the counterfactual that if this pen had been left unsupported (X), it would have fallen to the floor (Y). Neither X nor Y are true of the actual world. The pen was never removed from the table, and it did not fall to the floor. Take all X-worlds. The counterfactual $X \Box\!\!\rightarrow Y$ is true (in the actual world @) if the X-worlds in which Y is true (i.e., the pen is left unsupported and falls to the floor) are closer to @ than any of the X-worlds in which Y is false (i.e., the pen is left unsupported but does not fall to the ground, e.g., it stays still in midair). As Lewis (1986: p. 164) put it, "[A] counterfactual (...) is true if it takes less of a departure from actuality to make the consequent true along with the antecedent than it does to make the antecedent true without the consequent."

The key idea behind the possible-world semantics is that in specifying the truth-conditions of a counterfactual conditional, we should imagine a state of affairs in which X obtains and which is such that all *else is pretty much as they actually were*. But as noted already, this is not quite possible. In the possible world in which X did happen, many other things (including the laws) were different from the actual world @ in which X did not occur. Can we find comfort in the notion of comparative similarity? Now, although 'comparative overall similarity' is not defined strictly, a lot can be said of it. Notably, it imposes a weak ordering on the set of possible worlds that are accessible from @, that is, the relation of comparative similarity is connected and transitive. (It also imposes a centering assumption: @ is closer to itself than any other world is to it.) More important, however, similarity is clearly not one dimensional, but rather it is the result of many component similarities. Lewis (1986: pp. 47–48) ranked possible worlds according to the following dimensions of similarity (put in order of importance):

- Avoid big, widespread violations of the laws of nature of the actual world (very important).
- Maximize the spatiotemporal perfect match of particular matters of fact.
- Avoid small, localized violations of the laws of nature of the actual world.
- Secure approximate similarity of particular matters of fact (not at all important).

So, a world W_1 that has the same laws of nature as the actual world @ is closer to @ than a world W_2 that has different laws. But insofar as there is exact similarity of particular facts in large spatiotemporal regions between @ and a world W_3, Lewis allows that W_3 is close to @ even if some of the laws that hold in @ are violated in W_3.

All this implies that there is quite a lot of vagueness in the notion of overall comparative similarity, which accounts for the fact that counterfactuals themselves are vague, at least in the sense that it is a contextual matter as to what to keep fixed and what to change when we assert a counterfactual conditional. A more serious worry relates to the issue of the motivation behind the foregoing ranking of dimensions of similarity among worlds. It has been observed by many that Lewis's initial theory yielded the wrong truth-values for a type of counterfactual conditional that can be schematized as follows:

$$X \Box\!\!\rightarrow \text{BIG DIFFERENCE}.$$

For instance:

(C) If the president had pressed the button, a nuclear war would have ensued.

Intuitively, (C) is true. But on Lewis's initial account, it would be false. For a possible world W_1 in which the president did press the button and a nuclear war did erupt is more distant from (because more dissimilar to) the actual world than a world W_2 in which the president did press the button but, somehow, a nuclear war did *not* follow. Addressing this worry, Lewis noted that intuitive judgments of the truth and falsity of counterfactuals are prior to the similarity relation that is required for the semantics of counterfactuals; hence, the similarity relation should be such that it tallies with the right intuitive judgments concerning counterfactuals. The similarity ranking is meant to solve this problem. To see how the foregoing counterfactual is indeed true, Lewis invited us to consider the following: Take a world W_1 in which nothing extraordinary happened between the president's pressing the button and the activation of the nuclear missiles. In W_1 the nuclear war did erupt. Take, now, a world W_2 in which the president did press the button, but the nuclear war did *not* follow. For this to happen, many miracles would need to take place (or, to put it in a different way, a really *big* miracle would have to occur). For all the many and tiny traces of the button pushing would have to be wiped out. Hence, appearances to the contrary, W_2 would be more distant from (because more dissimilar to) actuality @ than W_1. The *big* violation of laws of nature in W_2 is outweighed by the maximization of the perfect spatiotemporal match of particular matters of fact between W_1 and @. So, with the help of the refined criteria of similarity among possible worlds, the president counterfactual becomes true. Still, one may follow Horwich (1987: pp. 171–172) in wondering how psychologically plausible Lewis's theory becomes: The similarity criteria are so tailored that the right counterfactuals become true, but they have little to do with our pretheoretical understanding of judgments of similarity.

As noted in relation to the 'support' view, an adequate theory of counterfactuals has to jump two hurdles. The first relates to cotenability. Lewis solved this problem by taking it that some conditions S are cotenable with X (the antecedent of the counterfactual $X \Box\!\!\rightarrow Y$) if some X-world is closer to the actual world than any not-S world. The second hurdle relates to the distinction between laws and accidents. Here, the possible world approach is on safe ground, although the ground can support any decent theory of counterfactuals. David Lewis (1973) revamped a long tradition that goes back to John Stuart Mill, via Frank Ramsey, according to which the regularities that constitute the laws of nature are those that are expressed by the axioms and theorems of an ideal deductive system of our knowledge of the world, and in particular, of a deductive system that strikes the *best* balance between simplicity and strength. Simplicity is required because it disallows extraneous elements from the system of laws. Strength is required because the deductive system should be as informative as possible about the laws that hold in the world. Whatever regularity is not part of this *best*

system, it is merely accidental. The gist of this approach is that no regularity, taken in isolation, can be deemed a law of nature. The regularities that constitute laws of nature are determined in a kind of holistic fashion by being parts of a structure. An advantage of this approach is that it can sustain, in a noncircular way, the view that laws can support counterfactuals for it identifies laws *independently* of their ability to support counterfactuals.

A key objection to the possible world approach to counterfactuals is that counterfactual conditionals are not purely objective; an irremediably subjective element enters into the judgment of similarity (and arguably, to the distinction between laws and accidents). Not only are the truth-conditions of counterfactuals "a highly volatile matter" as Lewis (1973: p. 92) himself noted, but also which counterfactuals are true turns out to depend on various partly nonobjective judgments concerning similarity weights and conversational contexts. This objection, however, might not be as fatal as it first seems precisely because counterfactual conditionals should not be taken to be pointers to necessary connections, powers, and the like but rather (in either of the two theories we have examined) summaries of attitudes we have toward statements that are supposed to express a *connection* between a hypothetical antecedent and a consequent. To exploit an idea of Sellars's, the core idea behind counterfactual reasoning is to assert that there are not good inductive reasons to affirm simultaneously a generalization and the physical possibility of an exception to it.

Counterfactuals and Evidence

Whichever way counterfactuals are treated, a particularly acute problem seems to arise, especially for empiricists: How are they connected with the available evidence, which can be gathered only in the actual world? To put the point differently, there cannot be an empirical test for a counterfactual by realizing its antecedent. The supporters of the 'metalinguistic view,' especially Mackie, avoid this problem by taking the counterfactual claim to be licensed by good inductive evidence. The advocates of the possible worlds approach pin their hopes on the role laws play in the truth-conditions of the counterfactuals. In particular, the thought is that although counterfactuals are about other possible worlds, these are *very much like* the actual world; hence, the evidence gathered in the actual world can be evidence for the truth of a counterfactual, by supporting the laws that back a similarity claim between the actual world and the world in which the antecedent of a counterfactual obtains.

Rubin's and Holland's Model

A promising model of counterfactuals, which aims to offer empirical test-conditions for them, has been developed by Donald Rubin (1978) and Paul Holland (1986) and has attracted increasing interest among statisticians and social scientists. This model focuses on the discovery of the effects of causes. Suppose, to use a simple example, we want to find out whether taking an aspirin makes a difference to a *specific* subject's relief from headache. We would like to give a certain subject u an aspirin to see what happens to the headache episode – let's call the result Y. Ideally, we also would like, *at the same time*, to withhold giving aspirin to the very same subject u, to see what happens to the headache episode – let's call this result Y'. The difference, if any, between Y and Y' naturally would be considered the causal effect of aspirin-taking on the headache episode of subject u. But this kind of experiment is impossible: The experimenter cannot give and *not* give an aspirin to the *same* subject u at the *same* time. Rubin's and Holland's main idea is that an appeal to counterfactuals allows us to make an inference about the causal effect.

Let's consider a population U of individuals, or units, $u \in U$. In a typical experiment, the experimenter applies one treatment, say i, out of a set of possible treatments T, to each unit u and observes the resulting responses Y. The experimental units are chosen and separated into two groups (the experimental group and the control group) by randomization. To simplify matters, let the treatment set T consist of two possible actions (treatment – t, and control – c). For instance, t may be taking the aspirin and c may be taking a placebo. Let Y also consist of two possible responses, for example, headache relief – Y_t, and headache persistence – Y_c. Although it is crucial that each unit is potentially exposable to any one of the treatments, to each unit u just one treatment is *actually* given, that is, either t or c. Similarly, for each unit u, there is just one response that actually is observed, that is, either $Y_t(u) = Y(t, u)$ or $Y_c(u) = Y(c, u)$. Rubin's model defines the two responses in subjunctive–counterfactual terms. $Y(t, u)$ is the value of the response that would be observed if the unit u were exposed to treatment t and $Y(c, u)$ is the value that would be observed *on the same unit* u if it were exposed to c. A key assumption of Rubin's model is that both values $Y(t, u)$ are $Y(c, u)$ are well defined and determined. In particular, it is assumed that even if subject u actually is given treatment t and has response $Y(t, u)$, there is still a fact of the matter about what the subject's u response would have been, had she been given treatment c. The task is to figure out the *individual causal effect*, that is the difference

$$\tau(u) = Y(t, u) - Y(c, u), \qquad [1]$$

which measures the effect of treatment t on u, relative to treatment c.

In each particular experiment, either $Y(t, u)$ or $Y(c, u)$ (but not both) ceases to be counterfactual. Yet, given that one of $Y(t, u)$ and $Y(c, u)$ becomes testable, the other *has to* be untestable. Holland has called a situation such as this "the *fundamental problem of causal inference*." Does it follow that figuring out eqn [1] is impossible?

Suppose that we give treatment t to u and we observe $Y(t, u)$. The question then is how could we possibly figure out the counterfactual value of $Y(c, u)$? According to the present model, when *certain assumptions are in place*, there are ways to assess counterfactuals such as the above. Here is how:

Given that unit u got treatment t, we may try treatment c to a *different* unit u', which is very much like u, except that it was given treatment c instead. That is, instead of testing the counterfactual conditional $Y(c, u)$, which is impossible, we test the indicative conditional $Y(c, u')$ – the response of unit u' if she is given treatment c – and claim that this tells *indirectly* what the value of $Y(c, u)$ is. For this move to be plausible at all, we need an assumption of *unit homogeneity*: that u and u' are so similar

that the actual response of u' to treatment c is the same as the response that unit u would have to treatment c. Under this assumption, we take it that $Y(t, u) = Y(t, u')$ and $Y(c, u) = Y(c, u')$. Then, the individual causal effect can be calculated, since eqn [1] becomes thus:

$$\tau(u) = Y(t, u) - Y(c, u) = Y(t, u) - Y(c, u'). \qquad [2]$$

Although eqn [1] involves essentially a counterfactual conditional ($Y(c, u)$), eqn [2] does not. Eqn [2] is indeed testable, but the counterfactuals are gone. Instead, eqn [2] has two indicative conditionals, one for unit u who received treatment t and another for unit u' who received treatment c. In a sense, the unit homogeneity assumption renders the counterfactual conditional $Y(c, u)$ not so much a claim about the *specific* unit u but rather a claim about *any* of the homogeneous units. It is because of this fact that the counterfactual is supposed to become testable.

We might proceed in another way to calculate $\tau(u)$. Instead of giving treatment t to unit u and treatment c to (uniform) unit u', we give treatment c to unit u at time t_1 and treatment t to the *very same unit* u at a later time t_2. This move requires another assumption, that is, *temporal stability* or the constancy of response over time. It also requires an assumption of 'causal transience' to avoid situations like this: The subject's taking a placebo at time t_1 changes some properties of her enough to affect her response to taking an aspirin at a later time t_2. Under these assumptions, we take it that $Y(t_{t_1}, u) = Y(t_{t_2}, u)$ and $Y(c_{t_1}, u) = Y(c_{t_2}, u)$. If this is so, then the individual causal effect can be calculated, because eqn [1] becomes:

$$\tau(u) = Y(t, u) - Y(c, u) = Y(t_{t_2}, u) - Y(c_{t_1}, u). \qquad [3]$$

The remarks made about eqn [2] can be repeated about eqn [3], too. Eqn [3] has no counterfactuals and it seems that the content of eqn [1] – which does involve the counterfactual $Y(c, u)$ – *reduces* to the joined content of two indicative conditionals $Y(t_{t_2}, u)$ and $Y(c_{t_1}, u)$ together with the two further assumptions of causal transience and temporal stability.

The key point then is that the alleged testability of counterfactual conditionals is predicated on the plausibility and success of certain general assumptions noted previously. These assumptions might fail. If, however, there are reasons to believe they do not, that is, if there is *evidence* for the general assumptions, then causal inference seems quite safe. I would suggest that these assumptions are characteristics of *stable causal-nomological structures*. Consider *unit homogeneity*. For it to hold, it must be the case that two units u and u' are alike in all causally relevant respects other than treatment status. If this is so, we can substitute u for u' and vice versa. This simply means that there is a causal law connecting the treatment and its characteristic effect, which holds for all homogeneous units and hence it is independent of the actual unit chosen (or could have been chosen) to test it. In effect, this holds for temporal stability too, since the latter is the temporal version of unit homogeneity.

Interventionist Counterfactuals

James Woodward recently has introduced the claim that only counterfactuals that are related to *interventions* can be of help when it comes to assessing their test or assertibility conditions. An intervention gives rise to an 'active counterfactual,' that is, to a counterfactual whose antecedent is made true by (hypothetical) interventions.

Woodward (2003: p. 3) characterized the appropriate counterfactuals in terms of *experiments*: They "are understood as claims about what would happen if a certain sort of experiment were to be performed."

Take Ohm's law (that the voltage E of a current is equal to the product of its intensity I times the resistance R of the wire) and consider the following two subjunctives:

1. If the resistance were set to $R = r$ at time t, and the voltage were set to $E = e$ at t, then the intensity I would be $I = e/r$ at t.
2. If the resistance were set to $R = r$ at time t, and the voltage were set to $E = e$ at time t, then the intensity I would be $i^* \neq e/r$ at t.

According to Woodward, we can perform the experiments at a future time t^* to see whether (1) or (2) are true. If, however, we are interested in finding out what *would* have happened, had we performed the experiment in a past time t (although we never did), Woodward invited us to rely on the 'very good evidence' we have that the behavior of the circuit is stable over time. Given this evidence, we can assume that the *actual* performance of the experiment at a future time t^* is as good for the assessment of (1) and (2) as a *hypothetical* performance of the experiment at the past time t.

An obvious advantage of this approach is that the truth-conditions of (the right sort of) counterfactual conditionals are not specified by means of an abstract metaphysical theory, as in the possible worlds approach. But there is a residual tension in this view. Woodward (rightly) insisted that counterfactual conditionals have determinate meaning and truth-conditions independent of the actual and hypothetical interventions. So there is a distinction between truth-conditions and test-conditions for a counterfactual. But then there must be a way for counterfactuals to get their truth-conditions fixed independent of their test-conditions. It is not quite clear what this way might be. The unclarity is accentuated by the fact that if there is such a way to specify the truth-conditions of a counterfactual conditional independently of its test-conditions (which are related to hypothetical interventions), then this way will offer truth-conditions to counterfactuals that do not (or might not) have test-conditions at all.

What if we were to collapse the truth-conditions of counterfactuals to their test-conditions? One can see the prima facie attraction of this move. Because evidence-conditions are specified in terms of actual and hypothetical experiments, the right sort of counterfactuals (the active counterfactuals) *and only those* end up being meaningful and truth-valuable. But there is an important drawback. Recall the subjunctive assertion in (1). On the option presently considered, what makes (1) true is that its evidence-conditions obtain. Under this option, counterfactual conditionals lose, so to speak, their counterfactuality. (1) becomes a shorthand for a future prediction or the evidence that supports the relevant law. If t is a *future* time, (1) gives way to an indicative conditional (a prediction). If t is a past time, then, given that there is good evidence for Ohm's law, all that (1) asserts under the present option is that there has been good evidence for the law.

In any case, Woodward is keen to keep evidence- and truth-conditions apart. One option would be to tie the truth-conditions of counterfactual conditionals to *laws of nature*. It then is easy to see how the evidence-conditions (i.e., actual and hypothetical experiments) are connected with the truth-conditions of a counterfactual: Actual and hypothetical experiments are *symptoms* for the presence of a law. Be that as it may, it is hard to see how a counterfactual can be assessed without taking into account the evidence there is about laws of nature or other general assumptions.

Causation and Powers

Despite the various difficulties we have presented, counterfactual conditionals are a stable part of the philosophical arsenal. Their being modal in character has invited the thought that they can capture a special connection between the antecedent and the consequent – most typically *a causal connection*. According to a popular counterfactual analysis of causation, to say (roughly) that event *c* causes event *e* is to say that *e* is counterfactually dependent on *c*, that is, that if *c* had not happened, *e* would not have happened either. This idea goes back to David Hume, but has been developed by Lewis (1974) into a full-blown theory. The sufficiency part of the definition is straightforward: If two events *c* and *e* are actual, and *e* is counterfactually dependent on *c*, then *c* is the cause of *e*. *Example*: Let *c* be the actual short circuit and *e* be the actual fire. If it is the case that if *c* had not occurred, then *e* would not have occurred, then the short circuit is the cause of the fire. But causation is transitive, whereas (as we have seen) counterfactual dependence is not. *Example*: Let *e′* be an effect of the fire *e*, for example, that the owner of the burnt house got some insurance money. If *c* causes *e* and *e* causes *e′*, then *c* causes *e′*. Although the owner's insurance compensation (*e′*) is counterfactually dependent on his house getting fire (*e*), which, in turn, is counterfactually dependent on the short circuit (*c*), *e′* is not counterfactually dependent on *c*: The owner would have got the insurance compensation (*e′*) even if the short circuit (*c*) had not occurred, assuming that the fire was caused in some other way. To make counterfactual dependence a necessary condition for causation, Lewis introduced a way to enforce the transitivity of counterfactual dependence: The sequence of events must form a *causal chain*. A sequence of events $<c, e, e', \ldots>$ is a chain of causal (counterfactual) dependence if *e* causally (counterfactually) depends on *c*, *e′* causally (counterfactually) depends on *e*, and so on.

This position, intuitively compelling though it may be, faces a number of important difficulties that has led to various ad hoc additions and modifications. (For a discussion of them see my 2002 paper.) The key point is that this approach explains how the effect *depends* on the cause without entailing anything as to how the effect is *connected* to the cause.

Those who think that there is a special kind of *connection* between cause and effect take counterfactual dependence to be a symptom of the presence of a power in the cause to bring about the effect: Causation amounts to a power's producing its manifestation. (This idea goes back to Leibniz who took it that causes are 'producers'). Actually, ascription of dispositions to objects (e.g., fragility or elasticity and the like) has been analyzed in terms of counterfactual (and subjunctive) conditionals. So, to ascribe a disposition F to an object *x* is to say that if *x* were to be given stimulus S, the characteristic result would be R. *Example*: *x* is fragile if and only if *x* were to be struck, it would break. Rom Harré and Edward Madden (1975) offered a general analysis of powers along the foregoing lines: *x* has the power to F if and only if *x* were subject to stimuli or conditions of an appropriate kinds, then *x* would do F, "in virtue of its intrinsic nature." So power-ascriptions to objects is analyzed in terms of (1) a specific counterfactual conditional and (2) an unspecified categorical claim about the nature of the object.

Despite its initial promise, this view faces important counterexamples, most of which point to the claim that the meaning of dispositional ascriptions cannot be captured by counterfactual conditionals. For it is possible either that the antecedent of the counterfactual is realized and the characteristic response does not obtain (e.g., because something else blocks the manifestation of the disposition) or that a disposition exists even if there are no manifestations of it (and hence no relevant counterfactuals to be entailed by it). Hence, the power-based attempts to understand the causal connection should either dissociate causation from counterfactuals or take "being disposed to" as a special (not further reducible) relation (see Mumford and Anjum, 2011).

Abstract

After a general introduction, historical overview, and a brief discussion of the philosophical roles of counterfactuals and various accounts of them, we emphasize counterfactual reasoning within the quantitative frameworks of probability theory, decision theory, and game theory.

Counterfactuals: History and Background

Counterfactuals are a species of conditionals, although various authors have struggled to delineate exactly *which* species. They are typically sentences with the subjunctive form 'if it were the case that *A*, then it would be the case that *B*,' or 'if it had been the case that *A*, then it would have been the case that *B*,' or equivalents – for example, 'if Gore had won Florida, he would have won the election.' *A* is called the antecedent, and *B* the consequent. Some authors distinguish counterfactuals syntactically from indicative conditionals, regarding the subjunctive mood as the hallmark of the former and the indicative mood as the hallmark of the latter – for instance, 'if *A is* the case, then *B is* the case.' Others draw the distinction semantically, corresponding to two different ways of supposing something to be the case. Counterfactuals usually involve entertaining *hypothetical* or *nonactual* states of affairs: the antecedent is believed or presumed to be false, or contrary to the fact, but its truth is imagined or supposed. Counterfactual reasoning is thus a form of *modal* reasoning, kindred to reasoning about necessity or possibility, and usually in contrast to reasoning about the way things *actually* are, for which indicative conditionals are thought to be appropriate. (Usually, but not always, consider "if the patient had the measles, he would be showing exactly these symptoms" (Anderson, 1951).)

The philosophical study of conditionals goes back at least as far as the Stoics of ancient Greece, although their systems of logic apparently did not accord the counterfactual any emphasis. The rise in interest in counterfactuals has been comparatively recent in the history of philosophy. In the 1940s and 1950s, philosophers began to argue that counterfactuals are closely associated with various important concepts – for example, confirmation, induction, and laws of nature (Goodman, 1947, 1954). Since then, counterfactuals have been employed by some philosopher or other in analyzing most other modal concepts – for example, dispositions (Ryle, 1963), causation (Lewis, 1973), necessity and possibility (Williamson, 2005), and essences (Brogaard and Salerno, 2007). In the past couple of decades, a large literature has emerged on causal modeling, in which counterfactuals play center stage in the interpretation of causal graphs and structural equations (Pearl, 2000; Woodward, 2003). Counterfactuals also feature in the analyses of other concepts that involve some robust, non-accidental basis – often regarded as one of causation or at least stable covariation – such as perception (Lewis, 1980), knowledge (Nozick, 1981), and explanation (Woodward, 2003).

The significance of counterfactuals has also become increasingly appreciated in the social sciences – by psychologists (e.g., in understanding emotions such as regret), by historians (e.g., in studying the incremental contribution by some commodity to economic growth), in political science (e.g., in imagining that a party's rise to power would not have occurred without a certain pivotal event), and so on. In the law, the standard method of establishing a defendant's culpability for some harm is the 'but for' test, which invokes a counterfactual: but for the defendant's action, would the harm have occurred? Sociologists often appeal to counterfactuals in their causal analyses. It is no surprise that counterfactuals are a central area of study in linguistics.

However, some philosophers are suspicious of counterfactual analyses of other notions, and even of counterfactual themselves. Shope (1978) finds many such analyses to commit a 'conditional fallacy' – notably, neglecting cases in which realizing the antecedent of a counterfactual used to analyze such a notion interferes with realizing the notion itself. One may wonder what the 'truthmakers' for counterfactuals could be: in virtue of what are some true and some false? Some authors doubt that they even have truth values at all, as we will see.

This brings us to the so-called *problem of counterfactuals*, raised by Chisholm and Goodman in the 1940s: that of providing adequate (in particular, noncircular) truth conditions for the counterfactual. A widely agreed upon analysis of counterfactuals has proved elusive, and some philosophers are reticent about using them to do foundational philosophical work partly for this reason.

The Analysis of Counterfactuals

Let '$A \mathrel{\Box\!\!\rightarrow} C$' denote a counterfactual with antecedent *A* and consequent *C*. Fixing the truth value of *A* and *C* clearly does not fix the truth value of $A \mathrel{\Box\!\!\rightarrow} C$. For example, we may suppose that 'if I were to drop this fragile glass, it would break' is true, and 'if I were to drop this fragile glass, it would turn into a hamster' is false, yet the antecedents ('I drop this fragile glass') and consequents ('the glass breaks,' 'the glass turns into a hamster') are all false. This rules out as an adequate analysis the *material conditional* $A \supset C$ (defined to be equivalent to 'not-A or C'), which is automatically true when *A* is false.

Nor it seems can the counterfactual be analyzed simply as a *strict conditional* $\Box(A \supset C)$, a material conditional governed

by a *necessity* operator, familiar from modal logic: $A \supset C$ is true not just as a matter of fact, but necessarily so ('in all accessible worlds,' as this is usually understood). Certain inference rules that are valid for the strict conditional are apparently not valid for the counterfactual – for example, antecedent strengthening:

$A \mathrel{\Box\!\!\rightarrow} C$, therefore $(A \,\&\, B) \mathrel{\Box\!\!\rightarrow} C$ (for any B).

Consider: 'if I were to drop this fragile glass *and it were to land on a soft bed of feathers*, it would break.' This may well be false, while the original counterfactual (before the antecedent was strengthened with the italicized words) was true.

According to *metalinguistic* approaches, $A \mathrel{\Box\!\!\rightarrow} C$ is true if and only if A, together with suitable further premises (on one version, stating appropriate laws of nature and initial conditions), implies C. Mackie (1973) takes counterfactuals to be themselves elliptical presentations of such arguments, and thus lacking truth values altogether. The advent of possible worlds semantics for modal logics in the 1960s gave new direction to the analysis of counterfactuals. Truth conditions for them are proposed in classic works by Stalnaker (1968) and Lewis (1973).

Stalnaker motivates his account by the so-called Ramsey test for counterfactual reasoning: first, add the antecedent (hypothetically) to your stock of beliefs; second, make the minimal adjustments required in the rest of your beliefs to maintain consistency; finally, consider whether or not you then believe the consequent. Stalnaker's truth conditions are intended to apply generally to conditionals of the form 'if A, then C,' which Stalnaker denotes '$A > C$,' with just pragmatics distinguishing between indicative conditionals and counterfactuals according to him. He assumes that for each world w there is an ordering of worlds according to their 'closeness' to w – roughly, how little they differ from w (in appropriate respects). Call a world at which A is true an *A-world*; the proposition A is regarded as the set of A-worlds. His guiding idea is that

$A > C$ is true at a world w
if and only if
C is true at the closest A-world to w.

For example, we may say that at the world at which Gore wins Florida and which otherwise differs minimally from the actual world (e.g., he does not lose California, which he won in the actual world), he wins the election. Hence,

Gore wins Florida > he wins the election

is true according to the Stalnaker semantics.

Lewis rejects Stalnaker's assumption that, for any given w and A, there is exactly one closest A-world to w. Lewis's truth conditions are as follows:

$A \mathrel{\Box\!\!\rightarrow} C$ is true at w
if and only if
some AC-world is closer to w than any $A\overline{C}$-world, if there are any A-worlds.

For both Stalnaker and Lewis, the counterfactual is vacuously true if the antecedent is impossible – that is, there are no A-worlds. This yields results that some find unintuitive – for example, 'if 323 were prime, it would be divisible by 2, 4, and 16' seems to be *false* (Nolan, 2013). Cases like this motivate authors such as Nolan (1997) to extend the Stalnaker/Lewis analysis to 'counterpossible' conditionals, appealing to *impossible* worlds that may be closer or further from a given world. On the other hand, Fine (2012) rejects 'possible worlds' accounts of counterfactuals altogether (even restricted to possible antecedents), arguing that counterfactuals are not *intensional*: replacing an antecedent or a consequent with a logically equivalent sentence can change a counterfactual's truth value.

von Fintel (2001) offers a *dynamic semantics* for counterfactuals, according to which the utterance of a counterfactual $A \mathrel{\Box\!\!\rightarrow} C$ shifts the conversational context to one in which the accessible worlds include at least the closest A-worlds; the counterfactual is the strict conditional $\Box(A \supset C)$ *with respect to this newly altered context*. Leitgeb (2012a, b) gives a *probabilistic semantics* for counterfactuals: $A \mathrel{\Box\!\!\rightarrow} C$ is true at w iff the conditional chance of C, given A, at w is very high. 'Chance' is a probability measure that is objective, nonepistemic, and world-relative. This connects counterfactuals to the quantitative framework of probability theory, and in particular the notion of conditional probability. Other such putative connections have driven another important line of research, to which we now turn.

Probabilities of Counterfactuals

There has been much interest in the connection between *probabilities of conditionals* (of which counterfactuals are an important class) and *conditional probabilities*. Let P be the subjective probability function, so that $P(A \mathrel{\Box\!\!\rightarrow} C)$ is the degree of belief in $A \mathrel{\Box\!\!\rightarrow} C$. There are some reasons (linguistic intuitions, considerations stemming from the Ramsey test) for thinking that counterfactual reasoning is, or should be, subject to the following constraint:

(*) $P(A \mathrel{\Box\!\!\rightarrow} C) = P(C \mid A)$ for all A, C in the domain of P such that $P(A) > 0$.

$$P(C|A) = \frac{P(A \,\&\, C)}{P(A)}, \text{ if } P(A) > 0.$$

Stalnaker proposed a version of this identity for his conditional, which can be shown to vindicate his truth conditions above, and to vitiate Lewis's. In response, Lewis (most famously in 1976) proved a number of 'triviality results': under certain assumptions, the only classes of probability functions that can sustain (*) consist solely of members that take at most four values, and that are thus trivial. Since then, a number of authors have strengthened these results – see Eells and Skyrms (1994) for a collection of relevant articles.

One of the assumptions shared by these results is that conditionals have truth values, and correspondingly that the probability of a conditional is the probability of its *truth*. Edgington (2008) denies this, arguing that instead the probability of the counterfactual $A \mathrel{\Box\!\!\rightarrow} C$ is given by "your view about how likely it *was* that *C would have happened*, given that *A* had", a conditional probability relative to "a hypothetical belief state in a different context, normally that of an earlier time". She thus upholds a relative of (*), with suitable understanding of the probabilities on either side.

Moreover, an identity somewhat in the spirit of (*) *does* hold for the Stalnaker conditional (which *has* truth conditions). Start with probability function P. Among other things, P assigns probabilities to individual worlds. Define a new probability function P_A as follows: for each world w, P_A shifts the probability that P assigns to w to the closest A-world to w. P_A is said to be derived from P by *imaging on A*. Some authors model counterfactual reasoning by imaging (eschewing conditional probabilities as in (*)). Lewis (1976) shows that there is an intimate connection between the Stalnaker conditional and imaging:

$$P(A > C) = P_A(C) \quad (\text{for all } P, A, \text{ and } C)$$

The exploration of tenable variants of (*) is likely to continue to be a lively area of research.

Counterfactual Reasoning in Decision Theory

The distinction between probabilities of conditionals and conditional probabilities is important for *decision theory*, a normative theory of how one's beliefs and desires in tandem determine what one should do. Such a theory typically combines an agent's utility function u and probability function P to give a figure of merit for each possible action, called the *expectation*, or *desirability* of that action. Let $S_1, S_2, \ldots, S_n$ be a partition of possible states of the world. *Evidential decision theory*, as presented by Jeffrey (1966), measures the choiceworthiness of action A by a conditional probability-weighted average of the utilities of its possible outcomes (the conjunctions $A \,\&\, S_i$):

$$V(A) = \sum_i u(A \,\&\, S_i) P(S_i | A)$$

It thus prescribes that an agent act so as to maximize V. Various authors believe that evidential decision theory gives incorrect verdicts in Newcomb problem cases, in which an action is thought to be evidence for the obtaining of a given state, without in any way causing that state. This has led to the development of rival versions of decision theory, sharing the name *causal decision theory*, which replace the 'evidential' conditional probability weights with weights that are supposed to capture the agent's degrees of belief about the causal efficacy of the action in bringing about each possible state. Gibbard and Harper (1981), following Stalnaker, use probabilities of counterfactuals as the weights:

$$U(A) = \sum_i u(A \,\&\, S_i) P(A \Box\!\!\rightarrow S_i)$$

They then advocate the maximization of U. In an alternative formulation (e.g., Joyce, 1999), the probabilities of counterfactuals are replaced by probabilities of the states imaged on A. Proponents of the causal decision theory believe that it agrees with the evidential decision theory in unproblematic cases, and that it delivers intuitively correct answers in Newcomb problem cases.

Counterfactual Reasoning in Game Theory

Counterfactual reasoning can play a crucial role in the rational deliberation of two or more agents strategically playing against each other, their pay-offs depending on what they all do – the province of *game theory*. Paralleling the distinction we found in decision theory, Stalnaker (1996) distinguishes two sorts of counterfactual reasoning, *causal* and *epistemic* (the latter could also be called *evidential)*. In the former, agents reason about what would happen if they or others were to act in ways that they know or believe to be nonactual. In the latter, they consider how their own or others' beliefs would change if they were to learn things that they expect not to learn – for example, contrary to what is standardly taken to be common knowledge (and thus regarded as certain) by all the players, an irrational choice is hypothetically made. Indeed, such (epistemic) counterfactual reasoning leads naturally to some important refinements of Nash equilibrium, such as Selten's subgame perfect and ('trembling hand') perfect equilibrium.

Various models have been proposed of how an agent's beliefs are disposed to change in the face of unexpected actions by others, and the consequences of such dispositions for rational action – see, for example, Bicchieri (1988) (for extensive form games) and Stalnaker (1996) (for normal form games). Closely related is Shin's (1989) theory of equilibrium in normal form games. He gives a counterfactual-based account of rationality – a rational agent never acts in such a way that he would have done better had he acted differently – and proves that his account is equivalent, under certain assumptions, to those that employ game theory's standard solution concepts of Nash equilibrium and correlated equilibrium. Skyrms (1998) integrates the themes that we have discussed in this and the previous two sections. He gives a probabilistic theory of subjunctive conditionals that finds its inspiration in (*), with 'assertability value' replacing the 'P' on the left-hand side, and expectation of conditional chance replacing the right-hand side. He then uses this theory to give a unified treatment of counterfactual reasoning in individual decision theory, and in normal form and extensive form games.

Finally, more and more sophisticated probabilistic models have been developed for the representation of conditional beliefs in games. The economists Battigalli and Siniscalchi (1998), for example, construct a space of infinite hierarchies of conditional probability systems in which one can represent any statement about the players' dispositions to hold (arbitrarily high order) beliefs regarding the other players.

Counter-Insurgencies and the Social Sciences

Abstract

This article takes a look at the contributions made by social sciences to the American counterinsurgency projects initiated during the Cold War in Asia and Latin America. Numerous research projects – many of them canceled before launch – were created to gather demographic, sociological, anthropological, and psychological data to contribute to 'developing' regions' social control.

After playing a peripheral role in World War I (WWI), primarily a chemists' and physicists' war, social sciences acquired higher scientific status and legitimacy as a result, among other reasons, of their use in World War II (WWII). Production planning and supplies' allocation, psychological recruiting and warfare, the use of media to raise both troops' and civilians' morale with propaganda provide but a few examples of social sciences' contributions during WWII. Military institutions profited greatly from sociology in this period. This social science contributed to such institutions by improving areas such as military labor selection and management issues, organizational effectiveness, motivation and morale, leadership, relationships between commands and chief-of-staff personnel, communication, organizational change, and unit efficacy criteria.

After the end of WWII, the race for world supremacy bore its impact not only on science but also on political and intellectual fields. The Cold War changed academic structures and discipline contents considerably. Disciplines concerned with social life aspects were encouraged to build on behavioral sciences in the search for social control and regulation. While, in the early 1940s, the war had been the focus of attention, throughout the (dawn) Cold War years, scientists focused on the revolution–counterrevolution–counterinsurgency triad. And, though the revolution had not been left aside, as it was a central Marxism phenomenon, starting in the 1950s, it garnered growing interest and concern, and it was even explored with greater scientific rigor (Bottomore, 1983).

Social sciences' contributions to counterinsurgency operations can be traced back to countless ventures initiated by former colonial powers. This dictionary entry takes a look at social sciences' contributions in counterinsurgency projects launched by the United States after the beginning of the Cold War. As a result, it also excludes the counterinsurgency efforts by the other dominant bloc after WWII, the Union of Soviet Socialist Republics, due to lack of access to Soviet and Russian archives and language barriers to use literature and documentary sources.

During the Cold War, the knowledge, experience, and fieldwork of social scientists – especially, anthropologists, sociologists, and psychologists – became remarkably important for military operations as well as for espionage and intelligence actions. Particularly, American social sciences stood at the service of their homeland's military apparatus, with a clear focus on foreign policy making. The overriding goal was to stop Communism around the world and to gain a better understanding of 'the Communist Mind' (Solovey, 2001a: 175).

Thus, social sciences turned to serve counterinsurgency, with close ties to decolonization and modernization processes in the so-called Third World during the second half of the twentieth century. (It is impossible to overlook an earlier instance in which military support and funding encouraged the development and growth of some social sciences. In the early twentieth century, anthropological studies garnered significant attention from military agencies wanting to gain a better understanding and insight into *cultural others*. Starting in the 1920s, it was common for many renowned anthropologists to collaborate with the U.S. Office of Strategic Services (OSS) – perhaps the most salient being British anthropologist Gregory Bateson, who collaborated with the American Army on several research studies, including the one in New Guinea that led to the publication of his book *Naven* in 1936. Bateson and his wife, Margaret Mead, conducted field studies, coproduced ethnographic films, and filmed photographic documentaries on Bali. Mead also collaborated with several U.S. military institutions, producing brochures for the Office of War Information and carrying out a study on the feeding and cultural habits of American citizens of foreign stock for the National Research Council. With Bateson and Geoffrey Gorer, she also helped the OSS establish a psychological training unit to prepare individuals for warfare in Asia and the Far West.) American academia largely viewed developing societies as characterized by persisting class, race, religion, or caste notions as well as irrational values. The fact that the political and military power could lure and coopt social scientists meant, in disciplinary terms, that high militarization and social control levels in these developing nations might lead to cultural, democratic, and political stability, while helping to secure strong economic growth. However, data were lacking, and, so, a number of quantitative, demographic, and geographic research programs were launched to raise enough information – figures, data, scientific, and empirical knowledge – to serve international social control. For the military, the promises brought by social sciences – either in terms of statistical analyses, by means of behavioral psychology studies, or anthropological reports on the cultures of the countries and peoples studied – hinged on the possibility to predict insurgent or revolutionary groups' actions and attacks. Thus, the prevailing practice intended to render social sciences much more empirical and quantitative.

More recently, several studies (Chomsky et al., 1997; Diamond, 1992; Simpson, 1998; Solovey, 2001a,b) take a look inside academia, turning them into study objects. These research efforts focus on the relationship between several sciences, universities, and the military – or what has also been called 'the construction of the military – scientific complex.' Thus, these analyses lies a number of questions on the ties between power and knowledge, politics and universities, state funding and the development of study or research fields, as well as the creation of research centers reporting to official, military, intelligence, or propaganda agencies. The intervention of security agencies changed academics and set the pace for its development, particularly in the early Cold War years, providing support to institutions, books, methodologies, programs, and disciplinary branches – including development studies, area studies, research on communications, and Operation Research (Simpson, 1998). This was the setting for a process of increasing respectability for social sciences in the United States, also supported by the construction of the so-called military–industrial–academic complex or the engagement of social sciences in the Cold War under military–government sponsorship (Solovey, 2001). In this process, the existence of a clear boundary between politics and scientific research did not exist – rather, it was actually and often blurred and undistinguishable.

Counterinsurgency in Asia and Vietnam's Centrality

One of the areas that received many counterinsurgency missions as a result of applied military anthropology was Southeast Asia. After WWII, this region became a very relevant economic, geopolitical, and strategic focus for the United States. Japan's reconstruction and its return to the regional economy turned Southeast Asia into a source for raw materials and market opening. It was deemed crucial for U.S. security to forge an agreement with Japan as an alternative to communist China's power in Asia. Indeed, operations were conducted in countries like the Philippines, Malaysia, New Guinea, and Indonesia. The bulk of America's presence and intervention in this Asian region would clearly start to unfold with the Vietnam War.

In the 1960s, U.S. counterinsurgency policies included programs for a type of economic, political, and social development intended to strengthen studied countries' social stability (Solovey, 2001: 195). The United States was back then – as it is now – the leading disseminating hub for the knowledge produced by social sciences (UNESCO, 2010). The theoretical–methodological framework developed by structural functionalism and abstract empiricism dominated that time with *modernization* standing out as prevailing paradigm.

Walt Whitman Rostow had published his *The Stages of Economic Growth: A Non-Communist Manifesto* in 1952, arguing that economic development unfolded in a number of stages that went from the basic economy of more traditional societies to the economy of scale of more developed, capitalist societies. Rostow was appointed national security advisor by President John F. Kennedy in January 1961. Shortly after his appointment, Rostow was asked to meet with Kennedy to discuss several threats to the U.S. national security and foreign policy associated with the Vietnam War. A few days later, Kennedy approved Vietnam's Counterinsurgency Plan.

American Secretary of Defense Robert McNamara characterized the conflict in Vietnam as 'the social scientists' war.' Indeed, throughout its duration, it was clear for the U.S. that a new approach was necessary to address Vietcong's resistance, and the use of social sciences was then deemed strategic. For instance, the Strategic Hamlet program was launched in 1964, initially to study Malaysia and the Philippines, but it later focused almost entirely on Vietnam. The program goal was to massively develop strategic villages and to strengthen farmers' settlements opposing the communist-led guerrilla forces. The underlying theoretical framework was based on a nation-building approach, as the plan hinged on expanding government services to these settlements, providing them with schools and roads as well as fostering local self-governance institutions, and promoting national values and symbols. To execute this program, Maynard Weston Dow, a U.S. Naval Academy graduate recruited by the Defense Department, collected sociogeographic data by means of household surveys for Vietnam's rural population. A while later, Dow himself submitted his doctoral thesis, under an U.S. Air Force Academy scholarship, entitled "Counterinsurgency and Nation Building: A Comparative Study of Post World War II Anti-Guerrilla Resettlement Programmes in Malaya, the Philippines and South Vietnam," at Syracuse University (Martin, 2013). Dow claimed that the Strategic Hamlet program was poorly managed and relatively ineffective in Vietnam (Dow, 1966), but it did account for an early American counterinsurgency attempt merging social sciences and a nation-building project. This type of programs was even viewed as potentially fruitful for other countries in Africa, Latin America, and Asia, when it came to collecting a large number of data on local populations and their loyalty or opposition to insurgent movements.

In 1966, the United States started its Civil Operations and Rural Development Support Program (CORDS) in Vietnam to bring peace to the country, joining military actions with economic and social programs based on theoretical models drawn from political sciences, sociology, and statistics. Specifically, the most outstanding contribution provided by CORDS consisted in a large amount of statistical data produced by the first information program dedicated to insurgent operations (Belcher, 2012: 261). These statistical data were used by the U.S. Army for its military interventions in Vietnam.

At that time, a program of psychological operations and interventions called *Chieu Hoy* (Open Arms) was also launched to persuade Vietcong fighters to desert. By 1967, some 75 000 desertions had taken place, but the program proved a failure, as the Vietnamese people and army was characterized by cultural and psychological resilience (Beckett, 2001). In addition, as revealed by Irving L. Horowitz (1972), a group of social scientists from Michigan received CIA funds to advice South Vietnam's police. At the same time, in 1967, the Advanced Research Projects Agency and the University of Pennsylvania were reported by students from Michigan and Cornell Universities for the development of Project Agile, a research initiative geared to counterinsurgency action in Thailand. In March 1970, a number of documents stolen from a university professor file surfaced, apparently implicating several social scientists in the U.S. counterinsurgency programs in Thailand.

These documents were delivered to the Student Mobilization Committee to End the War in Vietnam and were later published by *The Student Mobilizer* (Wolf and Jorgensen, 1970). A number of anthropologists and social scientists had allegedly gathered data for the U.S. Defense Department and for Thailand Royal house with a view to fostering a counterinsurgency program that would use development aid to ensure that tribal peoples remained loyal to Thailand's government (Council of American Anthropological Association, 1971).

Counterinsurgency in Latin America and the Paradigmatic Project Camelot

In Latin America's case, as politics grew increasingly more radical in some countries after WWII, the United States became more concerned about political developments inside its influence area. As a result, its attention, resources, and research efforts focused on this region. This scenario gathered momentum with the success of the Revolution in Cuba (1959), and the fear of immediate revolutionary guerrilla expansion – an exaggerated expectation that permeated both opposing sides – propelled the measures that had been brewing earlier. In addition to open and covert military interventions, the United States zeroed in on economic cooperation and counterinsurgency to fight communism.

John J. Johnson's *The Military and Society in Latin America* (1964) is a defense of U.S. political influence in favor of military intervention in Latin America. At the same time, a group of young officers – most graduated from West Point – was sent by the Pentagon to the Hilton Institute, a military base in South Carolina, to acquire strategic and sociological knowledge on Latin America to serve as the Pentagon's counterinsurgency 'experts.' Some of these officers would later stand behind the scenes at the military coups staged in the region (Chilcote, 1997).

This setting served as a backdrop for the creation of Project Camelot, a social science research study intended to measure, anticipate, and control internal conflict in peripheral countries. While it just illustrates the variety of research conducted in the Cold War and in the fight against insurrection, Project Camelot may very well be regarded as the most ambitious, straightforward, and crass example of the ties between social sciences and counterinsurgency as well as of the intervention and autonomy loss in science. This project started at American University's Special Operations Research Office and was commissioned by the U.S. Department of Defense to focus on Chile for a 4-year period. After Chilean–American anthropologist Hugo Nutini made several fruitless attempts to recruit Chilean social scientists for the initiative, Project Camelot was doomed to oblivion. When it seemed a thing of the past, the project made the headline at the leftist newspaper *El Siglo* as part of the United States' espionage. The news grew into such a scandal that Chile's political leaders were forced to create a Special Investigation Commission, reporting to the Chilean House of Representatives, to look into the matter.

Project Camelot's ultimate goal was to create knowledge to gauge the potential for domestic unrest, to estimate its effects, and to establish adequate control and normalcy restoration mechanisms in peripheral countries. The U.S. Army was endowed with the ability to "plan and lead operations involving a broad scope of the social and political issues that are part of counter-insurgency operations. Thus, the Army must develop doctrines based on an adequate knowledge of these areas" (Project Camelot Working Papers, 5 December 1964).

The Camelot scandal brought about a number of consequences. On the one hand, it led to the cancellation of similar projects across Latin America. As a result, Project Simpatico in Colombia and Project Colony in Peru did not take off. On the other hand, Camelot fueled a strong debate on external funding for Latin American social sciences. Suspicions about both outside financial support for disciplines and their utilization as espionage or cultural imperialism instruments turned into a myth of scientific research's direct dependence from the United States and its imperialistic 'uses.' These negative representations of science funding and use spread to any type of external support for scientific projects. This debate encompassed financial, structural, agenda setting, and research focus issues, as well as the role academics should play amid political radicalization processes. Its largely antiimperialistic rhetoric focused on the relationship between university and any American – public or private – agency. Philanthropic foundations, scientific institutions, universities, business companies, and government were viewed as cultural facades for the United States' security agencies.

Project Camelot was planned in Latin American social sciences' consolidation period, which came alongside an internationalization process – that is, as new places were created to house and develop them, these disciplines were partaking increasingly of the world's academic system. Counterinsurgency research projects emerged in a setting that welcomed these disciplines – Sociology, particularly in American science – and introduced them to the academic world, albeit without losing their peripheral standing. As these studies became public, a shadow of doubt was cast over all social sciences and their possible uses. However, at the same time, many social scientists were forced to stand up for their work. Sociologist Clodomiro Almeyda, an important Chilean socialist leader, tried to safeguard techniques when he noted that widespread rejection to Project Camelot "has an innocent casualty, smearing social research techniques – and, particularly, surveys" (Última Hora, 07/17/65: 2).

Some Final Remarks and a Brief Digression to the Present

Alas, this short historical review has shown how social sciences – particularly, anthropology, sociology, and psychology – have contributed to the counterinsurgency fight that the United States has waged in the second half of the twentieth century. A bulk of current literature has discussed these phenomena in a conspiracy-riddled tone. However, this analysis has chosen a more objective approach to depict these projects' interventionist and imperialistic nature. In any case, the engagement of social sciences in these studies was, for the most part, intended to produce statistical data – on demographics, geographical information, and on satisfaction/dissatisfaction with political regimes – that would contribute to anticipating and offsetting insurgency movements.

Counterinsurgency and academic knowledge militarization continue to be relevant topics today. The repercussions of the

events of 11 September 2001 marked the beginning of a new stage in the close relationship between counterinsurgency, social, and behavioral sciences, as shown by the U.S. military intervention in Iraq and Afghanistan as part of the so-called war on terror. Starting in 2003 in Afghanistan and in 2005 in Iraq, Provincial Reconstruction Tams, combining military officers and civilians, have been deployed to promote reconstruction efforts, to further security sector reforms, and to help expand central governments' authority in these countries (Marston and Malkasian, 2008).

In 2006, the U.S. Army launched its Human Terrain System, an US$-200-million program intended to combine anthropologists and other social scientists' work with combat units' daily tasks in Iraq and Afghanistan. The goal of the program was to collect data on these societies' human and cultural behavior, storing and disseminating this information to use it as leverage and combat weapons against insurgent forces. The Human Terrain System program was characterized as a mechanism to improve American military knowledge on local cultures and populations, using a software provided by the British firm BAE Systems. These measures replicate the vulgar terms of modern counterinsurgency, developing, creating, and producing statistical algorithms that try to predict insurgent actions but largely fail to capture key cultural, sociological, political, and psychological traits. As a result, these campaigns tend to be doomed, failing to accomplish their goals, as clearly shown by the U.S. failed attempts to sever ties between local insurgency and transnational terrorist networks.

When the U.S. Army and Marine Corps published their Counterinsurgency Manual in December 2006, Baghdad was in flames. Published with the University of Chicago's academic credentials, the manual was praised by think tanks and scholars for its fresh approach to war. Nonetheless, upon its debut in Afghanistan in 2009 under Barack Obama's administration, the doctrine proved to have little tactical success, wiping out villages and leaving a trail of dead civilians on its wake. These events call for a reflection on and a probe into the ethical and intellectual dilemmas brought about by the mobilization of human and social sciences in the field of counterinsurgency.

Abstract

This article explores the social logic of adjudication and locates it in context of other forms of legal dispute resolution. In so doing it relates adjudication within the political regime within which a system of adjudication is situated, pressures to settle rather than have a judge-imposed zero-sum solution, and the elusive concept of judicial independence.

Introduction

Adjudication is a type of dispute resolution that relies on an independent, third-party facilitator (Eckhoff, 1966; Shapiro, 1981). Such triadic relationships range from a mutual acquaintance who may serve as a go-between to help conflicting friends, to a powerful state which imposes a resolution on warring neighbors. Within the legal context there are three distinct types of dispute resolution triads: the mediator, the arbiter, and the judge. While all are engaged as third-party resolvers of disputes, they represent a continuum along which the freedom of the parties to the dispute is progressively limited. A mediator will facilitate communication between conflicting parties and perhaps propose a solution, but the parties themselves must agree to this solution. In contrast, an arbiter is a third-party decision-maker, selected and granted authority by the parties to impose a binding resolution. Adjudication is distinguished from both mediation and arbitration in several ways. Judges are usually externally appointed by the state and parties have no or very little control over who is selected to hear their dispute. Judges impose authoritative outcomes, but unlike arbiters, judges are expected to render their decisions according to preestablished norms. Furthermore, unlike mediation, adjudication does not require the active consent of the parties, though great efforts are made to secure consent or at least the appearance of consent.

Because their proceedings do not require the active consent of all parties, courts face a crisis of legitimacy. As a consequence, they must find substitutes for consent.

These substitutes can be understood as a set of principles (Cappelletti, 1989). The more important of these are the principle of party participation, the principle of the rule of law, the principle of impartiality, and the principle of independence. Indeed these principles have come to be understood as the defining characteristics of courts. The principle of party participation assures that those likely to be affected by a court's decision have an opportunity to make arguments and offer proofs in their behalf, but it also requires that the court respond with reasoned arguments to these concerns (Fuller, 1981). This principle may help account for the propensity of courts almost everywhere to encourage settlements in lieu of full-fledged trials and to value confessions of guilt or acknowledgments of liability. Although such practices have the obvious benefit of reducing the costs and risks of trial, they also provide – even if only symbolically – the active consent of the defendant to the process. The principle of the rule of law prohibits judges from making ad hoc decisions; it requires them to render decisions according to preexisting norms, the rules of the game which both parties have used (or are free to use) to organize their expectations and to arrange their affairs. Both party participation and the rule of law can be understood as approximations for consent. Participation provides parties with a voice and requires that their concerns be addressed; the rule of law presumes a shared set of norms or at least a set of rules under which all the parties operate. As we shall see, the rule of law is not a necessary condition for judicial independence, though it is closely associated with the notion of judicial independence (*see* Rule of Law (and Rechtsstaat); Criminal Procedure: Adversarial and Inquisitorial Legal Systems).

The principle of impartiality requires that judges have no interest in the outcome and no reason to favor one party over the other. This is usually achieved through the nature of the office; full-time judges, whose compensation is not dependent upon the outcome of the controversy, do not have any personal interest in the outcome of the controversy or ties to the parties of the dispute.

The related principle of judicial independence holds that the judge is not only independent of one or the other of the parties, but is also independent of other influences as well; the judge's full fidelity is to the rule of law. This poses an obvious and important challenge and may be the most difficult of the principles to implement. At times those not party to a dispute, such as an industry or trade association may have an interest in pressing for a particular outcome in a case or for a particular interpretation of a rule. More challenging still is that, as officials of the state, judges may be under pressure to adhere to political concerns rather than to the rule of law. Indeed, these two concerns are not always clear and separate. Almost everyone would agree that judicial independence is likely to be jeopardized if political authorities dismiss or force the resignation of judges with whom they disagree or if courts routinely uphold edicts of the regime that have not been duly enacted. A more subtle problem of judicial independence arises when the state enacts new laws, resists interpretative approaches of the judges, removes issues from the jurisdiction of courts, and seeks to influence judicial selection.

Similarly the issue of independence arises when judges make policy. Typically judges make policy when they confront

new situations not covered by existing doctrine or when existing doctrine contradicts deeply held personal or widely supported social norms. In such situations, courts may continue to apply outmoded norms. However, courts might alternatively create new doctrine through any of several institutional devices, such as the use of fictions (Fuller, 1981), reliance on metaphors, and reasoning by analogy (Levi, 1961), or treat vague and open-ended provisions in constitutions or statutes as grants of authority authorizing them to make new law (Feeley and Rubin, 1998). In any of these situations, judges can be criticized for abandoning the rule of law and hence for compromising their independence. Yet judges who insist on following outmoded or restrictive laws also run the risk of being criticized for failing to act independently and for being subservient to an unpopular regime or a new regime. Independence surely means more than freedom to apply a narrowly prescribed process of interpretation.

No one seriously argues that the modern state lacks authority to enact a wide variety of laws (though constitutional safeguards, conceptions of individual rights, and the like may severely constrain what the state may do and how it must enact laws). Still, the rule of law requires that laws be duly enacted, and publicized. At a minimum an independent judiciary is one which honors and upholds these procedural limits on state power. Still, governments, particularly new regimes following major political realignments or revolutions, may exert strong pressures on the judiciary to fall in line with the 'spirit' of the new regime. The new regime may be impatient with the slow pace of change through the rule of law or may react to what it perceives as a conservative judiciary wedded to the old order; it might exert pressure upon the judiciary to look at things in a new way. Such pressures can take any number of forms, including requesting judicial resignations, altering the procedures for judicial selection and advancement, selecting new judges whose views are aligned with those of the new regime, demoting judges deemed to be recalcitrant, or simply ignoring judicial actions that are deemed unacceptable. This is more difficult in democratic regimes since they are all more or less committed to respecting judicial independence.

Thus it would be a mistake to treat the issue of judicial independence as a problem faced only by authoritarian or totalitarian regimes (Ginsburg and Moustafa, 2008). In modern states everywhere, judges are governmental officials. In democracies, both the law and the constitution are understood to be products of popular will. Courts everywhere are likely to be affected by, shaped by, and at times in conflict with larger governmental processes in ways that raise issues about the independence of the judiciary. Indeed, since much of the legitimacy of modern government is closely tied to a belief in majoritarian principles and to the rule of law, conflicts between government and courts are all but guaranteed in all sorts of political regimes. This complex relation between law and government, adjudication and politics, and courts and governmental regimes is addressed in the sections below.

Judicial Independence

The quest for judicial independence in common law and civil law systems has taken quite different forms, though the differences may be due less to the particular legal forms than to the political systems in which they are situated. With the rise of absolutist states in early modern Europe and continuing well into the twentieth century, the judiciary was strongly integrated into the machinery of government, and courts were well-known as arms of the ruling regimes. With the rise of support for constitutional democracy in Europe, reformers sought to institutionalize the principles of the rule of law and judicial independence. One of the main objectives of constitutionalism is "to limit the arbitrary exercise of power and make it legally accountable" (Sartori, 1987). Although the rule of law is embraced in all constitutional systems, it has taken quite different forms. In countries with traditions of strong states (which historically have drawn their judiciaries into the service of the state), judicial independence has been pursued by integrating the judiciary into the structure of the civil service, by developing comprehensive codes of law so that laws are understood as bureaucratic-like rules, and by characterizing judges as technical experts. Judges are free to pursue their duties, but within these severe constraints. This conception of the separation of powers and judicial independence assumes the primacy of the legislature; the legislature represents popular will, and courts play a subordinate although independent role in finding facts and applying rules. Thus in strong states, judicial independence is purchased at the price of a narrow conception of the judicial role.

One can see this in the judiciaries of countries with a civil law tradition, where law is understood as a set of technical rules and judges are considered to be technicians (Merryman, 1985). And one can see it in some authoritarian states, where judges have sought to protect themselves by defining their roles narrowly and by insisting on strict interpretations of the law. But where the law involves politically salient issues – such as labor relations or economic regulations – governments everywhere are likely to remove jurisdiction from ordinary courts and establish specialized tribunals more directly responsive to political controls to deal with disputes. Thus in all countries, a large group of disputes between citizens and the state do not fall under the jurisdiction of independent courts but are assigned to specially created administrative tribunals that are more responsive to governmental direction. Similarly, issues of constitutional interpretation and judicial review, i.e., the power of courts to declare actions of other branches of government unconstitutional, have generally been removed from ordinary courts and assigned to more politically responsive bodies (Stone-Sweet, 2000). As a result, many – perhaps most – disputes between citizens and the state do not fall under the jurisdiction of ordinary courts, but are instead assigned to special administrative tribunals which are constructed precisely in order to be responsive to governmental interests.

Thus in disputes between individuals which are not likely to raise political controversy, judicial independence is protected, but where issues which may be politically charged, a more politically responsive judicial institution has been established. In a variation on this theme, Damaska has argued that, in regimes with a tradition of a strong or activist state, courts are designed and expected to implement government policy (1977), while in common law countries with traditions of weak states, judicial independence has been protected in a quite different way. Ironically, such common law political

systems with weak states tend to foster 'strong' courts. Indeed, the law – and courts – have been considered to be to some degree autonomous from the state (Feeley, 2013). In these countries the independence of law is protected not so much through a careful civil service-style judiciary and minutely crafted legal codes, but through a robust legal profession that has close associations with the judiciary. Although here too judges are officials of the state, they are also regarded as an integral part of civil society and are closely associated with an autonomous legal profession (Halliday et al., 2012). Constitutionalism and the rule of law are understood not only as procedural constraints on the government; they are external limits on the state as well. Ironically, this conception of the limited state produces a strong judiciary and an expansive notion of judicial independence (Damaska, 1986).

It is important to underscore some of the salient differences produced by these two conceptions of courts and of judicial independence. In Europe, independence is secured by subordinating the role of judges to the democratic principle – the will of the people expressed through parliament – and by insisting upon detailed codes so that judges have no need to make law but only to apply it (Guarnieri and Pederzoli, 2002). Typically this is reinforced by a career judiciary whose initial selection and subsequent promotions are based on seniority or merit. In contrast, common law systems entrust substantial law-making powers to the courts, since the law itself is conceived as something independent of the state and politics. Although there is an admitted political feature to judicial selection, judges are recruited from senior members of the bar, continue to maintain close ties to the bar, and are not dependent upon political authorities for support. Countries elsewhere have often adopted a hybrid of American-like and Continental institutions, though in all but former British colonies, the result has been much closer to civil law than common law style structures.

The differences between civil law and common law systems are familiar to anyone with some exposure to comparative law. Yet these differences only identify central tendencies; legal systems are too varied and too complex to be divided into any such neat categories. For instance, in continental systems even the most comprehensive code is not likely to anticipate all problems that may come within its scope; as a result a judge may have to make law to fill in the gaps. Similarly, law-making in modern common law countries is no longer primarily judge-made; modern law everywhere is increasingly statutory and administrative. Moreover, since the late twentieth century, the independence of civil law judges has been strengthened. In many countries, the government no longer controls judicial careers and judges have begun to play a more active role in law-making (Guarnieri and Pederzoli, 2002).

Furthermore, judicial independence – of either variety outlined above – is much more likely to occur in regimes with competitive political parties. Almost everywhere, one-party or predominant-party states have constrained the independence of the judiciary and sought to use it for their own political purposes (Ramseyer, 1994). Conversely, countries with competitive parties which alternate in controlling the government or where political parties are weak (e.g., Italy and Israel in the late twentieth century) are more likely to have independent judiciaries. Although all political victors may be tempted to convert the judiciary for their own use, those knowing that they may hold office only temporarily may resist the temptation in order not to jeopardize their long-term interests. Recognizing the harm that each party could impose on the others, parties in competitive political systems all have an incentive to maintain an independent judiciary (Landes and Posner, 1975).

The Business and Organization of Courts

The popular image of trial courts is that they try cases and resolve conflicts. But a careful examination of the process of adjudication reveals a more complex picture. The vast majority of all cases disposed of by courts – perhaps as many as 98% – are resolved by the parties themselves, without a full-dress trial. Indeed, in many instances, there is no expectation of a trial. In civil cases, court filings are often treated as signals to the opposing party that the other person is serious about pursuing his or her grievance. This is often enough to precipitate negotiations and resolution. Similarly, in criminal cases in both civil law and common law countries, most matters are disposed of without sustained judicial involvement in a trial, through unilateral prosecutorial decisions to drop charges, plea negotiations, or simply pleas of guilty. Indeed, in many countries, vast numbers of lesser criminal cases are disposed of through the mail without even a single court appearance by the accused (Feeley, 1979; Felstiner, 1979). In many of these situations, some combination of the prospects of the cost, time, and embarrassment of a trial is enough to encourage the parties to negotiate a settlement in the shadow of the courthouse (Mnookin and Kornhauser, 1979). Still, in such situations, the court may have been actively involved in the preliminary stages of the process, and may have handed down important pretrial rulings dealing with the scope of discovery, the admissibility of evidence, and the like. Such rulings provide cues to the participants as to the likely outcome of their case and thus precipitate negotiations and settlement rather than a prolonged trial process. In such cases, although the court did not formally resolve the conflict, it did nevertheless play an important role in its resolution.

The reasons for negotiations in the shadow of the law are fairly obvious. Filing a case often provides each party with the first opportunity to determine the strength of the opposition. This experience leads weak plaintiffs to drop their cases or to try to settle, and weak defendants to admit liability quickly or to settle. Cases that continue to trial are likely to be close cases in which both parties believe that they stand a good chance of winning. Economists have formalized this model, hypothesizing that, all things being equal, defendants would win (or lose) just as often as plaintiffs in full-fledged trials (Priest and Klein, 1984). Although uncertainty, changes in legal rules, and the degree to which an initiated case is controlled by the court can affect this dynamic, in the long run a stable equilibrium should prevail.

At the outset of this article, we noted that one of the problems of adjudication, in contrast to mediation and arbitration, is that the parties neither resolve their own dispute nor select the third-party decision-maker and that this can generate an aura of illegitimacy around the judicial process. If true, this may account for the ubiquitous tendency for parties to settle in the shadow of the courthouse and for courts to foster

settlement (Shapiro, 1981). Despite this, the tiny fraction of cases that go to full-dress trial provides the public with its perception of the nature of courts and adjudication.

In most countries trial courts are divided into two levels: lower courts which handle minor issues and upper-level courts which are reserved for a handful of more important matters. Although a substantially higher proportion of cases are resolved without formal or full-fledged trial in the lower courts, most issues reaching upper-level courts are also resolved through negotiations. Indeed, when all negotiated settlements and uncontested proceedings at both levels of courts are considered together, one finds that only a tiny portion of cases in trial courts of any sort are resolved through full-fledged adjudication (Trubek et al., 1983). As noted above, however, one should bear in mind that adjudication is a process that involves several steps. A party to a case may agree to settle only after a vigorously contested pretrial hearing that clarifies issues and may point to likely outcomes at trial. Although such dispositions are formally recorded as dropped cases or negotiated settlements, the outcome was in fact the result of an adjudicated decision. This is not at all uncommon; many plea bargains in criminal cases occur only after a contested motion to suppress evidence. As trial procedures have become more complex over the past two centuries, it is not surprising that much important adjudication has been relocated to the pretrial process.

All modern judicial systems provide for some system of appeals. The scope of reasons for appealing a case varies widely in different legal systems, but it is safe to say that a primary purpose of appellate courts is to listen to those who lost at trial and those who claim that the trial court made a mistake. In some legal systems, an appellate court may only consider allegations of error by the trial court. In others, the appellate court can undertake something of a trial *de novo*, and can reconsider facts introduced at the original trial and, in some places, consider additional facts brought to light since trial. In all this, appellate courts service two functions: they can correct errors, and they provide a regime with the ability to oversee and supervise the activities of a highly decentralized system of lower courts. By securing only a handful of appellate court judges sympathetic to its aims, a ruling regime can gain considerable assurance that justice will be administered within the bounds of its tolerance. This may be why civil law systems – that is active, policy-implementing states – tend to have more appeals (Damaska, 1977).

The common law tradition (Llewellyn, 1960) has always acknowledged the vast powers of courts to make policy, but since World War II, courts worldwide have embraced a more activist policy making stance (Tate and Vallinder, 1995; Stone-Sweet, 2000). A primary cause for this is the expansion of judicial review, both in countries with long-standing histories of constitutionalism, and new countries with written constitutions that provide for judicial review. This has resulted in the emergence of a vast literature on the politicization of the judiciary (Ginsburg, 2003; Hirschl, 2004) and the judicialization of politics (Silverstein, 2009). The former is associated with various political issues, such as the war on crime, and with questionable judicial propensities to interpret narrowly rights of the accused and exercise sentencing discretion in tune to harsher popular sentiment, as well as rule in areas with high political saliency, such as expanding tort liability, increasing awards in accident claims, expanding the concept of implied warranties in contracts, expanding (or contracting) doctrine governing employment discrimination, class actions, and remedies in extended structural reform cases such as police use of force or conditions in prisons (Rosenberg, 2008; Epp, 2009; Farhang, 2010). The latter is associated with the extension of due process and related constitutional requirements to governmental agencies such as schools, police, prisons, and welfare agencies that have hitherto not been subject to such detailed scrutiny (Kagan, 2001; Feeley and Rubin, 1998; Silverstein, 2009). While these developments were generally initiated by courts in the United States, they have since spread to courts around the world, and the United States is no longer an outlier or even leader in these areas (Hirschl, 2004; Mate, 2012).

Conclusion

Adjudication is a triadic structure, involving two disputants and a judge who is charged with imposing a solution on the parties. The process is inherently unstable; the losing party is likely to feel that the judge sided with the other party. Courts have responded to this inherent instability in two ways. They have fostered judicial independence through the formalism of the rule of law ('Do not blame me, blame the law!') and everywhere courts tend to encourage parties to arrive at consensual or negotiated outcomes so that they do not have to impose a solution upon them. A cursory look at judicial statistics around the world reveals that courts are fairly successful at this. Indeed, there is now considerable concern about the 'vanishing trial' (Galanter, 2004). Still, it should be remembered that legal claims are often negotiated only after a court has issued a preliminary ruling that may all but signal the outcome after trial, and there is little evidence that precedent-setting appeals have declined. Ironically even as worldwide courts are reducing their adjudicative role in some areas as alternatives to adjudication and negotiated settlements have increased, they have expanded them in others. With the near universality of the embrace of the rule of law and judicial review, courts with greater independence in a great many countries have taken on increased political significance, in some instances handing down decisions that can either destabilize or reinforce the existing regime, and in others subjecting more features of government and the administrative process to more far reaching judicial controls (Kapiszewski et al., 2013).

Abstract

Social anthropology, grounded in participant observation, has addressed the topic of craft production during the twentieth century in several ways. The theoretical frameworks/approaches discussed here are concerned with: material culture and folklore; ethnographic accounts; Marxist studies; the cultural meaning of commodities; learning and apprenticeship; and craft production as 'niches' in the global economy. The latter is explored further by an examination of some of these niches in both developing and industrialized societies.

The familiar definition of 'craft' as a skill in making something, usually by hand, is essentially that used in anthropology. Political economists have distinguished between craftsmen who make things for use or sale to the consumer, and manufacture where things are made for merchants/capitalists to sell. Manufacture often involves several stages of production, either in the processing of raw materials (e.g., thread into cloth; weaving; dyeing) or of components (parts of a watch each made by a specialist craftsman; parts of a car). Before the industrial revolution the stages of manufacturing were coordinated and controlled by merchants or by the state, who had the necessary capital. While today manufacture refers to making things by machines, the literal meaning is 'handmade' (from Latin manus, 'hand' and facere, factum, to make). Pre-industrial manufacture involved coordinating the stages of handcraft production, and was widespread in some societies with complex economies (India, China, medieval Europe). Production of goods by hand today is often coordinated by middlemen (see below). Thus it is useful to include in craft production both the making of goods by skilled craftsmen, and the coordinated manufacture of handcrafted goods.

Craft Specialization, the Division of Labor, and Commodization

The division of labor by gender and age has been basic in human societies from the simplest hunter-gatherers through pastoralism, simple and more complex forms ofagriculture, to urban societies up until the industrial revolution, and remains important today. In small-scale societies where all adult men and women practice the same craft skills, these tend to be carried out as part of the domestic economy. Kin roles are also economic roles. In this 'domestic mode of production' (Sahlins, 1972), craft products are made for both use and exchange. Craft skills are learned from older same-sex kin in the course of assisting with craft production. The developmental cycle of the domestic group reproduces the unit of craft production.

As societies become larger and more complex, emerging urban centers can support craftsmen who specialize in a single product (iron knives, silk cloth, pottery for cooking). Repeatedly we find that specialized production is associated with refinements in technology. With a specialist division of labor, craft products become commodities as they are exchanged for other commodities or enter the market. Hart writes that the central feature of increasing economic complexity is the integration of the division of labor in a nexus of commodity production and exchange; and that there is a tendency towards the progressive incorporation of ever more aspects of social life as commodities. 'The commodity is human labor embodied in a good or service offered to society rather than be consumed by its producer. As such, com-modisation may be defined as the progressive abstraction of social labor' (Hart, 1982).

As the nexus of production and exchange becomes more elaborate, new patterns of the division of labor appear. This pattern can be seen in the independent towns of medieval Europe and the Mediterranean. In Europe in the Middle Ages, textile production for an expanding market became organized as manufacture, first in specialist guild workshops, and then in rural cottage industry which took two forms. Cottage-craftsmen and women raised or bought the raw materials which they spun and wove into cloth, and sold locally to merchant buyers. The cottage-craftsmen owned raw materials, tools, and the finished cloth, planned their own work, and dealt directly with the market, although vulnerable to its fluctuations. In the other form of cottage industry, merchant manufacturers supplied the thread, often the loom, and owned the finished cloth. Weavers were paid for their work, in effect selling their labors as cottage-laborers. Rural cottage craft production organized by merchant capital is an example of what has been termed 'proto-industrialization.' With the harnessing of water- and then steam-power the invention of machines to replace handcrafts skills became possible. Such machines brought workers into factories, but the organization of components of production in manufacturing remained in many ways the same (machines now did the work of spinning, warping, weaving, finishing, dyeing) (Goody, 1982).

Clearly, the industrial revolution has radically changed the conditions of craft production. It is no longer central to the production and exchange of commodities in industrial societies. Further, Western manufactured goods and industrial production have become integral to the economies of developing countries. Yet a number of niches of craft production remain. Social anthropology, grounded in participant observation, has addressed the topic of craft production during the twentieth century in several ways.

Theoretical Frameworks of the Anthropology of Craft Production

Material Culture and Folklore

The nineteenth century excitement with evolution was shared by anthropology, and carried over into the twentieth century with the Folklore school in which the study of material culture was central, especially in the United States and the Scandinavian countries. The focus was on detailed description and mapping of material culture, with a view of preserving a record of rapidly disappearing 'early' forms of society. Where craft production was treated it was within this framework.

Ethnographies in Social Anthropology

The ethnographies of this tradition took as problematic the social structure and functional integration of societies studied. Ethnographic accounts treat religion, kinship, economics, and political dynamics as all important and related. However social anthropologists differed in the weighting given to each domain, as did the societies they studied. Significantly, those ethnographers who treat craft production as a significant feature tend to have worked in relatively complex societies. Among them, Nadel's account of the kingdom of Nupe (Nigeria) is preeminent for its detailed accounts of a number of craft industries, and the way these relate to the Nupe court. Each craft is discussed in terms of the access to raw materials, technical processes, the organization of the division of labor within the workshop, authority and transmission of skills among craftsmen, design and fashions as these relate to consumer demand, and patronage by nobles and the court where this is relevant. Some crafts are 'open' in the sense that any man can learn by assisting a skilled worker (weaving, bead making); others are 'closed,' restricted to members of certain kin groups (blacksmiths, brass smiths). Craft skills are learned in informal apprenticeship. Closed crafts restrict apprenticeship to kin; this also serves to keep ritual and secrete knowledge within the craft kindered (Nadel, 1942). Miner's account of craft production in Timbuc- too in the same period is less detailed, but closely parallels that for Nupe (Miner, 1965 [1953]). Slave production of food stuffs and cotton was important, particularly in northern Nigeria, but does not appear to have been organized for craft production. However rural industry ofthe cottage craftsman kind in weaving and dyeing is documented around the city of Kano where certain villages were famous as centers of dyeing. The town of Daboya played a similar role as a center of dyeing in the precolonial textile industry of northern Ghana. (See also chapters by Pokrant and by Goody, in Goody, 1982.)

Marxist Studies of Craft Production

With its focus on modes of production, Marxist theory offers social anthropology a framework for the study of craft production. A mode of production consists of the productive forces (natural, material, and technical) and the social relations of production. Most work in this area is by French anthropologists, exemplified by an English collection of papers by French neo-Marxists (Seddon, 1978). The goal of this volume is to lay the groundwork for 'a truly scientific study of society … which will lead to the discovery of laws that underlie the development of … social and economic formations … (and) identify the relations of production characteristics of pre-capitalist formations' (Seddon, 1978: p. ix). There are chapters about self- sustaining agricultural societies, the peasant mode of production, the Asian mode of production, and an African mode of production. Based on detailed ethnography, most are rich and insightful discussions of the relations between economic and political factors, several foregrounding kinship in new ways; this is especially true of those in the section based on fieldwork in Africa. However, perhaps because their goal is the identification of general laws, craft production is not a focus of description or analysis.

Following the Seddon volume a number of anthropologists have written ethnographic studies of craft production from a Marxist perspective. Three can be noted briefly: Kahn's *Minangkabau Social Formations* (1980) is a study of village blacksmiths in Sumatra. He describes in detail technology, organization, and marketing – treating relations of production within the workshop, the pattern of learning craft skills, relations between blacksmiths, external influences such as imported materials, and tools. The analysis is set in the context of Minangkabau matriliny, a subsistence agriculture based on rice, and economic policies of colonial overlordship. Based on individual or small workshop production for a local market or to traders, this is petty commodity production.

The next example is a study of Scottish Hebridean Island weavers of Harris tweed. Ennew (1982) traces the development of this industry from the first sales of Harris tweed in 1881. From the beginning it was based on cottage-laborer production, with merchants supplying the wool, dyes, and often the loom, and deducting the cost from payment for the finished cloth. Demands from the external market (London, overseas markets) led first to the introduction of a wider, foot-powered loom, then to removal of warping to the spinning mills in order to control quality and patterns. 'From the moment of wool-purchase the production process of Harris Tweed is entirely in the control of mill-owning capital, except for the slight loss of control during the outworking [weaving] phase' (Ennew, 1982: pp. 189 – 190).

Very different relations of production characterize the manufacture of carved hardwood furniture in Hong Kong. In the factory which Cooper joined as an apprentice wood carver, identical sets of tables were carved for tourists and export. He speaks of the proletarianization of the industry. Workers were paid daily at an hourly rate; the factory products were standardized, carvers producing endless legs and tops for tables, with no involvement with design or contact with customers. However he does feel that seven months as a factory carver gave him insight into the Maoist distinction between manual labor and mental labor, into proletarian culture as well as ideology (Cooper, in Coy, 1989).

It seems that craft production is incorporated in several modes of production: petty commodity, cottage laborer, and even as proletarian labor.

The Rebirth of Material Culture Studies: The Cultural Meanings of Commodities

Material culture has again become a central concern for anthropology, but now the focus is on the cultural and personal meanings of things as commodities. Objects serve to

objectify cultural meanings in individual experience; individual identities are constructed through the consumption of commodities. Indeed it has been argued that the study of consumption and commodities represent a major transformation in the discipline of anthropology and may come to replace kinship as the core of anthropology. Appadurai, in his Introduction to *The Social Life of Things: Commodities in Cultural Perspective* (1986) reviews economic theories which focus on the production of commodities and argues, following Douglas and Isherwood, that the interesting questions are rather about why and how people consume goods. The factors that drive consumption (the 'demand' of classical economics) are to be found in socially and historically shaped cultural meanings – in the political economy of the social life of things. The Introduction concludes: 'Ever since Marx and the early political economists, there has not been much mystery about the relationship between politics and production. We are now in a better position to demystify the demand side of economic life' (Appadurai, 1986: p. 58). Given this perspective it is not surprising that among these anthropologists the few who are interested in production deplore the scarcity ofrelevant studies (but see chapters by Spooner and Bayly in Appadurai, 1986).

Learning and Apprenticeship in Craft Production

The learning of craft skills has consistently been central to craft production itself – with the domestic mode of craft production in simple societies, in apprenticeships in craft workshops, and again in the domestic mode of cottage industry production. Craft production is labor intensive, and the work of unskilled children and youths frees craftsmen to concentrate on more complex skilled tasks, assembly of components, and organization of both production and distribution to consumers. A Vygotskian view sees learning as based on working alongside an adept: observing, assisting with very simple task elements, gradually taking over responsibility for these elements while continuing to observe, and then assisting with more complex tasks. This model corresponds closely to the learning of weaving by fostered apprentices in the Daboya textile industry (Goody, in Goody, 1982). It also appears to fit accounts of domestic craft production by blacksmiths (Nadel, 1942; Kahn, 1980; Coy, 1989); it is consistent with formal apprenticeship as in industrial wood carvers (Cooper, in Coy, 1989) and Japanese folk potters (Singleton, in Coy, 1989). The contributors to Coy's edited volume on *Apprenticeship* (1989) are all anthropologists who did fieldwork while themselves apprenticed, and several learned handcrafts. Their work supports the view that in craft production the learner is central to the production process – by providing unskilled labor in labor-intensive production; by systematically enforced subordinate status which legitimizes labor demands and supports the expert's control of synchronizing elements of production; and by embodying the social reproduction of craft skills and knowledge.

Trajectories of Craft Production in a Global Economy

Before industrialization, virtually all artifacts – for daily use, exchange, luxuries – and the tools for making these, were the products of craft skills. With the industrial revolution, craft manufacture ('hand making') of most commodities has been replaced by machine production in factories. Yet today craft production still occurs in the many niches left by industrialization, sometimes in surprising places.

There are many craft production niches in both industrial and developing societies; this is an open set. The conditions under which handcraft production has advantages (of cost, of detail work, of skilled knowledge) are varied, and change in response to both local and global factors. Social anthropologists have studied craft production in some of these niches; other awaits research. Contemporary anthropology is responding to the complexity of globalization and postmodern skepticism of both theory and observation with a proliferation of particular interests. While none of the major current themes focuses on production, there are good individual studies in several of these niches. It is only possible here to sketch these briefly.

Niches of Contemporary Craft Production in 'Developing' Societies

Artisan/craft Production for Local Use in Developing Societies

In partially industrialized third world societies many commodities for local use are made by individual craftsmen and workshops, and in small factories, using handcraft tools and techniques. In Bolivia, tinsmiths make pails and basins, blacksmiths make farm implements and locks, others make kerosene lanterns, dancing masks, clothing, shoes, etc. (Buechler, in Coy, 1989). The largest single example must be the Indian Khadi cottage industry making handspun, hand woven cloth. Beginning in the ideology of self-sufficiency with which Gandhi led the movement for independence, this continues to be centrally organized. As with other attempts to make household craft production economically viable alongside industrial production, partially mechanized processes have been introduced to support handcraft skills (e.g., multiple-spindle spinning jennies are wired to electricity by villagers, Bayly, in Appadurai, 1986).

Artisan/craft Production in Developing Countries for the Global Market

There are two links to this market, tourists buying locally, and international buyers for stores in industrialized countries. The two are related, since tourists want to buy similar craft products on returning home, and consumers of craft producers in industrialized countries look for them as tourists. Social anthropologists have recently become interested in tourism. Among the studies which treat craft production are several in Graburn's *Ethnic and tourist arts* (1976); see especially the chapters by Graburn (on Inuit soapstone carving), Kent (Puebio and Navajo weaving in the American Southwest), and Salvador (on Mola applique blouses made by Cuna Indians).

Handwoven and hand-printed textiles have for centuries been among India's most successful export industries. In the twentieth century some firms concentrating on garment manufacture attempted to secure advantages of efficiency and control through factory production. However, there is a pattern of reverting to commissioning both weaving and making up of

garments from smaller units – cottage weavers and small workshops. Swallow's study of one such company finds that in a volatile export market the costs of factory production (maintaining plant and machinery, labor troubles) remain higher than those of cottage craftsmen and cottage laborers managed by intermediate capitalist merchants, under conditions of population pressure and lack of alternative unemployment (Swallow, in Goody, 1982).

An increasingly common pattern is merchant or factory production of crafts sold locally to Western buyers for retail in industrial countries. Best studied is the production and marketing of luxury goods such as oriental rugs/carpets (see Spooner in Appadurai, 1986) and carved hardwood furniture (Cooper, 1980). Less elaborate, cheaper craft products (simple jewelry, pottery, glass, textiles) are made by cottage craftsmen, cottage laborers, or in workshops for sale to wholesale buyers who market them in bulk to retailers at trade fairs in industrialized countries. These are finally sold to consumers in Western gift shops, department stores, and clothing stores (buyer, personal communication). Although this mode of craft production for final sale in the commodity-rich markets of the West probably far exceeds in volume that of luxury goods, it seems as yet not to have been studied by anthropologists.

Development Aid and Craft Production

International development agencies, nongovernmental organizations (NGOs), and national government agencies have seen craft production as a potential focus for income-generating projects, usually for women. This may mean building on existing craft skills; often crafts judged as marketable are unfamiliar locally, and have to be taught. Project effort is directed towards teaching skills, securing access to materials and tools, and marketing. The development of some form of local cooperative structure is often integral to the project. Although anthropologists often participate, little published material is available on such projects, except in the form of reports and evaluations.

Niches of Craft Production in Industrialized Societies

Outwork and Workshop Handcrafts in Industrial Societies

In industrialized societies craftsmen – here usually craftswomen – continue to work at home at piecework rates on a number of crafts: sewing on industrial machines (owned or rented), knitting (often by machine), and the making of small cheap goods like Christmas crackers. This modern cottage industry is cheaper for manufacturers for the familiar reasons: low rates of pay; a dependent labor force lacking employment alternatives; no need to maintain plant or machines; flexibility of labor force which is only given work when demand is high. Some manufacturers, particularly in textiles, bring craftspeople into workshops where sewing and knitting machines are provided and supervision is possible, making changes in design easier.

Production of Folk Crafts for the National Market

The 'Arts and Crafts movement' associated with William Morris in England in the second half of the nineteenth century had counterparts in the United States, and later Japan. This movement reacted to industrial production by romanticizing craft production, seeing it as preserving old techniques and a classical vision of beauty expressed in individual hand skills. In order to manufacture craft products so as to make them accessible to an enlightened market, Morris taught himself to weave, embroider, print textiles, make tied carpets, make glazed tiles, and block print designs used for wallpaper. Apprenticeship was initially rejected, since they were seeking a pure re-creation of the essence of each craft. Although it was Morris' dream to make craft products cheaply so all could afford them, the cost of production with skilled labor and costly materials meant they were always luxury goods.

This vision survived. It subsequently led to handcraft manufacturers using traditional patterns and materials but of relatively modest cost: of textiles (Harris tweed), pottery (exemplified by the craft of Bernard Leach), and in the United States of Quaker furniture. In Japan it was reflected in the deliberate creation of a word of 'folkcraft' *(mingei)* after discussions among artists and philosophers (including Bernard Leach), and the establishing of a national museum of folkcraft which worked especially with traditional potters to develop aesthetic and practical adaptations of old forms. This folk pottery was made in traditional rural workshops, and became commercially popular. In his study of several rural Japanese pottery-making communities, Singleton found that high demand led in some to an opening of apprenticeship to outsiders, with a decline in the authority of the master (Singleton, in Coy, 1989).

Persistence of Customized Craft Production

Factory production for mass consumption has become the major source of commodities in industrialized societies. Customised handcraft production continues alongside this, especially of men's clothing, women's fashions, shoes, and jewelry. Women's fashions have become international, with a few famous designers in Paris, Rome, New York, and Tokyo holding annual shows which set the latest fashion. At the luxury end of this mode of production the craftsmen designs a prototype made in his workshop; this may be commissioned by a customer, offered for sale through a show, or in exclusive shops. Successful designs may be copied in other workshops for sale in select stores; such as garment with a 'designer label' is still considered exclusive. A few designs are more widely copied and sold through chains of stores to the public. This 'trickle-down' of fashions through dressmakers' workshops has always linked dress to social mobility. Lace, from the sixteenth to the nineteenth centuries, moved from courts to town gentry to village bonnets. Maher describes this for Turin in the early twentieth century, where seamstresses copied the dresses made for customers to wear themselves – thus passing socially as ladies (Maher, 1987). Customized craft production also continues to be important, for instance in fine furniture, jewelry, pottery, and textiles. These are sold in specialist shops, and increasingly in shops alongside replicas of museum holdings. Their makers are coming to be known as designer craftsmen,' and also as 'artist craftsmen.' There is a debate, as with some of the ethnic crafts, as to whether this is 'art' or 'craft.'

Individual Craft Production for Pleasure in Using Craft Skill

The anthropological preoccupation with conceptualization of identity in terms of commodities has displaced earlier anthropological interest in occupational and personal identity based on skilled craftsmanship. Yet there is a resurgence of popular interest in learning craft skills like sewing, knitting, embroidery, lace-making, weaving, pottery, jewelry-making, etc. A number of indices reflect this enthusiasm: where they used to be learned from kin or in apprenticeship, such crafts are now taught in community centers and in summer workshops; practitioners form associations concerned with style and pattern, access to tools and materials, teaching and examining craft skills; there are magazines and books devoted to patterns and techniques; practitioners hold exhibitions of their work. The main motivation seems to be development and exercise of individual handcraft skills. Products are used by the maker or given as gifts. While occasionally a seamstress, weaver, or potter becomes skilled enough to sell skills or products on the market, for most commodization is not a factor. Indeed, individual craft production may be seen as the separation of craft skills from the market.

Creativity Training

Mark A Runco and Sarah E Sumners, University of Georgia, Athens, GA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Certain kinds of training purport to enhance creative performance and maximize creative potentials. Training may be short- or long-term and may include explicit directions or may be defined in terms of particular environments and contexts. Because creativity depends on cognitive processes that are not used unless an individual is motivated to use them, training often includes both affective and cognitive facets. The most effective creativity training efforts utilize most or all facets of the creative process. Although creativity can take many different forms, all creativity training assumes that there are in-born creative potentials and thus the most accurate way to describe training is the fulfillment of potential. This view implies that creativity training will have broad benefits, since potentials are universal. This article discusses training as enhancement and then reviews the cognitive, affective, and environmental training intentions and concerns. It concludes with educational recommendations.

One of the most important unanswered questions in the creativity literature is one that focuses on efficient and effective methods for the fulfillment of potential. This is the central question for educators who respect creativity, but it is also critical for organizations that wish to maintain or increase their innovation and productivity. It is relevant to studies of *positive psychology* and optimal development and related to both psychological and physical health, each of which seems to benefit from creative self-expression. In his book, *No Rootless Flower*, Frank Barron, one of the pioneers in the field of creativity studies, once remarked that creative expression and psychotherapy were complementary, the idea being that each could contribute to the other. Psychotherapy might help open the doors for creative self-expression. The more common method for fulfilling creative potential and performance involves systematic training, which is the focus of this article.

Although creativity can take many different forms, all creativity training has at its core the utilization of in-born creative potentials, and indeed the most accurate way to describe training (or education, or any effective treatment) is the *fulfillment of potential*. This indicates that training does not provide something that did not exist before; it merely releases and reinforces what the individual already possesses. It also acknowledges the fact that there are individual differences. Just as individuals vary in terms of their height or weight – each of these being the end result of an interplay of nature and nurture – so too do they differ in the potential for creative behavior. Not everyone could change the world with creative works, like Einstein or Picasso did, but everyone can fulfill potentials and reach the highest level of their creative talents – and thereby change their own worlds, even if not the entire globe.

Creativity is multifaceted. Scientific theories therefore refer to it as a *syndrome* or a *complex*. Most enhancement efforts focus on one single component rather than the entire complex. More often than not, enhancement also focuses on cognitive capacities and skills. This is one issue when considering the effectiveness of training because, although creativity often depends on particular cognitive operations and processes, these are not used unless the individual is motivated to employ them. Creativity is an affective, as well as cognitive phenomenon. Along the same lines, particular personality traits, such as openness to experience, may also be involved in creative work, and there are social, interpersonal, and contextual influences as well. This article focuses on the issue of enhancement and reviews various targets and a range of training methods, by carefully defining creative potential.

Training as the Enhancement of Potential

Defining training as the fulfillment of potential allows the recognition of all enhancement efforts, be they systematic or informal, or short or long term. Besides, by defining enhancement in this way, any controversy over the nature and nurture of creativity can be avoided. This follows from the idea that nearly all human potentials are both genetic *and* experiential, with experience (in the present context, the experience that leads to enhancement) working within genetic boundaries. Biologists refer to the *range of reaction*, with the range genetically determined, and the reaction within that range determined by the individual's experience. In this light, the enhancement of creativity merely fulfills an individual's genetic potential. It does not change the potential but insures that behavior is moved toward the high end of the range of potential. One might say that inborn talents are maximized. Some are born with greater potential than others; however, everyone has some capacity for original and creative expression. Given the importance of creativity for personal growth and social and technological evolution, we should consider carefully how best to fulfill the relevant potentials. As mentioned briefly above, one type of enhancement focuses on the cognitive basis of creative thinking and problem solving.

Cognitive Components

Various cognitive processes contribute to creativity. Some processes are more basic than others. They are purely cognitive (e.g., attention, memory, and information processing), while others involve higher-order thought (e.g., strategic problem

solving, metaphor, and divergent thinking). Metacognitive processes are frequently involved in cognitive theories of creativity because they refer to tactical and intentional operations, and creative work is usually both of these. Many creative persons make a habit of questioning assumptions, for example, or they may focus on doing what has not been done before. Some have as their goals personal paradigm shifts, their intent being to break new ground. They may stretch and extend ideas, approaches, or work in entirely new directions. They intentionally, and often strategically, target creative results. With the intentionality assumed by all strategic and metacognitive efforts, it is likely that the vast majority of all systematic enhancement training efforts attempt to improve creative thinking by providing appropriate tactics.

Table 1 presents a list of some commonly used tactics both in education and the business world employed to foster the creative process. Many of the tactics in Table 1 are interrelated. Many of them, for instance, involve some sort of shift in perspective. This is true of points (1)–(8), (12), (13), (18), (20), (23), (24), and (26) – and the benefit of several others may follow from a change in perspective. New perspectives disrupt mental sets and routines thereby minimizing the chances of fixity; often resulting in original ideas.

Most tactics (and training efforts) focus on originality, which is essential, although when taken alone not a sufficient indicator, for creativity. Keeping in mind that original insights are not always creative, consider points (9), (10), and (20)–(22). Some original insights are unusual, novel, or unique, precisely because they are worthless or inappropriate. They are not creative if only original. Creativity involves more than originality. Truly creative insights are original and somehow fitting or useful. Runco and Jaeger, in the 2012 *Creativity Research Journal*, referred to this as the *Standard Definition of Creativity*.

Table 1 Example tactics to improve creative thinking

1. Change your perspective.
2. Work backward, from the end of the problem (the solution) to the beginning.
3. Invert the problem. Turn it inside out, upside down.
4. Question your assumptions.
5. Get another opinion. Talk to someone from another field, or with a different perspective.
6. Incubate. Put the problem aside for a while.
7. Think like a kid. (What would your younger brother or sister say?)
8. Break the problem into small parts. Deal with the smaller versions.
9. Try new combinations.
10. Explore new connections.
11. Let your mind wander. Trust your intuition.
12. Be playful, foolish, uninhibited.
13. Use trial and error, especially the latter – and then learn from those mistakes.
14. Gather more data.
15. Think big! Think small! "Honey I shrunk the kids!"
16. Find an analogy. (The Wright brothers did it; they looked to birds!)
17. Find useful information or analogies in nature.
18. Visualize. Try 'the mind's eye.'
19. Change the medium. (Draw a picture. Make up a song about that problem.)
20. Explore the bizarre.
21. Be a 'contrarian.' Walt Disney was one – that's how we got Mickey Mouse.
22. Bend the rules! Dr Seuss made up how many new words?
23. Focus on quantity for a while. A high-quality idea may find a way out, eventually.
24. Borrow an idea and then make it better.
25. Ask questions. Ask: Why? How? Why not? What if?
26. Change the problem. Make it one that allows original solutions.

Many training efforts treat creativity as a kind of problem solving. Note, however, that some of the tactics given in Table 1 focus on a problem, and others focus on solutions. This is an important point because many creative ideas are attempts to solve problems. Others are creative precisely because they redefine a problem. With this in mind, it is not surprising that some tactics lead the individual to change the problem or its representation.

For the purposes of training it can be useful to define creativity as problem solving. This allows the training to be focused but it also means that at least two aspects of creativity are ignored. Not all creativity involves problem solving. Even when creativity is a kind of problem solving, the relationship is not a simple one. Problem solving is sometimes creative, but creativity may be manifested when the individual is not working on problems, or at least not solving them. The individual may have the need or urge for self-expression sans problems. From this perspective, creative thinking and problem solving are sometimes unrelated, but creative skills may be used for more than problem solving.

Tactics such as those listed above (and there are many others) are often included in the various systematic programs that are designed to enhance creativity. Gordon's well-known procedure labeled *Synectics* (from 1961), for example, encourages the use of analogical thinking. It is easy to see the power of analogical thinking in inventions such as the steam engine (a tea kettle), Velcro (clingy burrs), and the airplane (birds, to whom the Wright brothers looked many times). Here again there is an alternative, which in this case is that some creative thinking uses analogical reasoning, and some does not.

Even more systematic programs have developed around models of creative problem solving. There is the *Odyssey of the Mind*, for example, *Future Problem Solving*, and *Creative Problem Solving* (CPS). The last of these is probably the best known for its impact on divergent thinking. CPS relies heavily on *brainstorming*, where the quantity of ideas is targeted by a group while the quality is de-emphasized. Judgment and evaluation are postponed, and 'piggybacking' (extending ideas given by others, stretching a line of reasoning) is encouraged. Empirical research on brainstorming suggests that it is only modestly effective (summarized in a chapter by Tudor Rickards and Christian deCock, in 2012). In fact, if an organization really needs a large number of ideas, they may be better off having individuals work alone. Brainstorming may be good for team building, but it does not seem to work as well as for individual problem solving. Too often, individuals in brainstorming groups tend toward 'social loafing' and assume that others will do enough work to get the job done. Likewise, the creative process involves more than the quantity of ideas that brainstorming targets. Min Basadur's *Simplex* training targets problem definition and solution evaluation, as well as idea

generation. Basadur also is explicit in the training about cycling through the process as needed rather than simply going once through it.

Information Processing

Occasionally, enhancement efforts focus on basic facets of information processing rather than the meta-cognitive contributions to creative thinking (e.g., tactics). Note the label, 'information processing.' It is indeed a matter of processing, and usually this kind of training targets changes in information transfer rather than information storage (memory). This follows from the view that information storage capacity is static and largely, or even entirely, universal. The label focuses on 'information' because enhancement is expected when an individual stops treating information as factual in the static sense. This is another way of saying that the individual questions assumptions and shifts his or her perspective. Information is consciously examined and perhaps even altered, rather than merely transferred without question.

At other times, maximization of creative potential is expected when the individual is simply more knowledgeable, or at least has the most relevant data. Good information is very important for many creative solutions, in many domains, although of course quality is more important than quantity. In fact, individuals can apparently have too much information! When this occurs, there is a brand of expertise that leads the expert to assumption and a reliance on routines. In their 1995 article on the psychoeconomics of creativity Rubenson and Runco suggested that this is one reason why creative thinking becomes more difficult as we age. We have more information and make more assumptions. These preclude mindful and spontaneous thinking. Creative thinking is probably most likely where there is an optimal amount of information – more is not always better – and when the individual knows to treat information as contextual rather than absolute. Enhancement is most likely to lead to creative thinking when the individual is informed but, in addition, avoids the assumptions and routines that may preclude original thinking.

Motivation and Attitude

The most effective efforts to maximize creative potential are those that communicate the value of creative solutions and ideas. In addition to simply showing *how* the individual or organization can be more original, they show the *why* as well. This brings us to the extracognitive basis of creativity, including the motivational and attitudinal components of creativity which are important for the development of creative self-efficacy. Attitudinal changes may be necessary because people will need to expend effort to change their ways. They will need to break routines, to question assumptions, and to take risks.

Some individuals and organizations may assume that creative persons are eccentric, or even difficult to work with (because they do things their own way). In this light, one of the critical attitudes targeted in enhancement efforts is *tolerance*. People in organizations wishing to increase innovation and creativity must tolerate independence, risks, and perhaps a lack of structure. Educators must tolerate divergence in the thinking of the students. This can be especially difficult because so much of the educational curriculum (and assessment tradition) is convergent. Tests, for example, are most objective when there is one correct answer, rather than originality.

It would be difficult to overstate the role of motivation. Without it, individuals will not invest in the mindful information processing that was described above. If an individual is already motivated to act creatively, it may be a matter of supplying tactics, direction, or resources. If the individual is not motivated, or motivated to work in other ways (e.g., *satisficing*, or just getting the job done), the motivation to do creative work may be difficult to arouse. This difficulty in arousing motivation occurs because creativity efforts are typically intrinsically motivated by payment or rewards – contingencies and promises made by others. Rather, intrinsic motivation comes from within and is personal and independent of contingencies and promises. Moreover, extrinsic factors can undermine intrinsic motivation. For this reason, the creativity that results from intrinsic motivation to solve a problem or express oneself can be lost if it is not respected and if an effort is not made to reinforce or redirect it. This can make enhancement very difficult. On the one hand, motivation is required, but on the other hand, it is a kind of motivation that comes from within. This is why values should be targeted. If an individual values creativity, he or she will probably be motivated to express and apply it. Instead of rewarding, say, piano playing, it might be better to show how playing the piano improves the quality of life and allows a healthful self-expression. This is just one example, the point being that it is possible to avoid the *overjustification effect*, whereby intrinsic motivation is lost, if the training focuses on general values and the specific application of a tactic or action is left to the individual. Of some relevance is the finding from the meta-analysis of creativity training, prepared by Scott, Leritz, and Mumford and reported in the 2004 *Creativity Research Journal*. This analyzed 70 empirical investigations studies of creativity training and concluded that successful training should include examples of 'real-world' illustrations followed by a series of domain-specific exercises.

Environmental and Interpersonal Factors

Interpersonal and contextual influences on creativity are indicative of the need to respect intrinsic motivation and the need for tolerance in educational settings and organizations. Indeed, maximization of creative potential may result from the careful structuring of context as much as from direct and explicit training.

Creativity is supported by environments that allow autonomy and tolerance and provide the resources necessary for the individual to maintain independence. Tolerance for autonomous and diverse work styles and interests may be vital in most organizations, and any individual with an opportunity to behave in a creative fashion will probably need time. Time allows incubation and the exploration of alternatives. Admittedly, while deadlines and imposed schedules can constrain thinking, some famously creative persons have claimed that they worked best under pressure (e.g., with some competition).

This fits with the idea of creativity as intrinsically motivated. Each individual may have his or her own ideal context for creativity.

Creative processes often produce unexpected results. They are, after all, original, and original results may be at most only loosely associated with previous efforts. But the unexpected nature of creative insights means that there is a risk. Thus, a tolerance of risk and use of creative discretion, on the part of the individual and those working with the individual, is often necessary. Further, organizations must accept that risk if they wish to support creative and innovative thinking.

Conclusions

Enhancement of creative potential through training may involve explicit instructions or it may result from particular environments and contexts. Training efforts can be founded in the cognitive, metacognitive, motivational, or attitudinal facets of the creative process. The cognitive facets may be the easiest to target (e.g., by suggesting tactics) and the motivational, the most difficult, given the role of intrinsic interests, but the most effective enhancement will take most or all facets of the creative process into account.

Educational practitioners and managers should recognize the need for enhancement efforts. They may investigate the programs that are designed to maximize creative efforts, or they may take it upon themselves to create a stimulating environment and provide the respect, resources, and tolerance that will allow creative thinking. Enhancement is probably most effective over the long run if the training covers a period of time or is revisited. If the interest is in fulfilling the potential of children, parents are in the best position to enhance creative thinking. They can model creativity, provide opportunities for original problem solving and self-expression, and appropriately appreciate autonomy and risk taking – and they can do so for an extended period of time. If the benefits of enhanced creativity are recognized on a larger scale, by society as a whole, enhancement is virtually assured. If this occurs, parents, educators, managers, and supervisors will all tolerate, appreciate, support, and benefit from enhanced creative thinking.

Creolization: Sociocultural Aspects

Abstract

This article considers the usage of the concept of creolization in contemporary social sciences and raises questions about its relevance and usefulness for the study of contemporary sociocultural change. Topics covered include the origin of the concept, its appropriation by social sciences including anthropology, its various meanings and usage, and the various critiques that have been addressed to these.

The concept of creolization has been used in anthropology to refer to processes of social and cultural change that take place in societies characterized by rapid social flux and where cultural influences from various origins are integrated into a new locally produced system of meaning. The term is borrowed from linguistics, and used in analogy with the processes of language creolization that appeared in some types of sociolinguistic contact. Cultural creolization takes place during sustained cultural contact, more typically produced within the hegemonical conditions of colonization, World System influences, and globalization.

Over the years, creolization has been used in different ways: as a label indexing sociocultural changes associated with colonization in some parts of the world; as a metaphor capturing the elusive processes of integration of new cultural forms; as a synonym of hybridization associated with globalization; and as a model for the study of cultural change directly derived from the linguistic model of creolization. In all cases, the term refers to processes of social change and restructuration. An example of creolization, certainly not representative of all types and domains of creolization, would be a Solomon Island businessman sending printed invitations to the Catholic wedding of his daughter in the biggest hotel of the city of Honiara; yet, he would make sure to collect the bridewealth from the family of the groom, and would subsequently redistribute it to members of his lineage and clan according to preexisting obligations. The blending of the two practices gives new meanings and new salience to the formalization of the alliance between families, but also between the newlyweds.

The concept of creolization has been 'appropriated' by cultural studies, literary criticism, cultural geography, Latin-American studies, history in addition to anthropology and has provoked healthy debates within these disciplines, but also outside of academia. Indeed, as Romberg points out (2011), creolization and creoles have become a political terrain within academia and local interest groups. In the same vein, Stewart (2007) points to the multiplicity of meanings of 'creolization' and 'creole' and as applied to domains as diverse as race, diaspora, the body and theory. Discussions on the applicability of creolization to the study of social change usually address the nature of the creolization process itself, the relationship of creolization to globalization and to the concepts of identity, culture, and creativity.

One can ask questions about the current interest in creolization. Is this interest, for instance, indexical of current anthropology's interest and fascination for plural and complex societies (Benoist, 2013)? *Is creolization good to think*, as Aisha Khan asks, or is it merely a seductive *floating signifier* (2007: 665)? Does creolization offer a frame that facilitates the analysis of "*fluidity and unbounded nature and cultural processes*" in light of "*pre-existing cultural stability and continuity*" (Eriksen, 2007: 163)? Do creolized societies represent an ideal (Glissant, 2011) of cultural richness, transformation, and creativity that insufflate new blood into old veins?

The life span of creolization is also a subject of debate and a source of questions. Is creolization a transitional period in the life of societies, at particular moments of their history, or is it a permanent state of affairs? And if linguistics proves to be an appropriate model for social creolization, do the creole continuum and the concept of decreolization prove useful for analyzing the transformations of societies whose creolization has peaked, so to speak (Hannerz, 1987)? We can argue, as Eriksen (2007) does, that standardization constitutes a form of decreolization: as fluid cultural forms become cultural models, they are codified. But this begs the question: What is the life span of these codified cultural models? Will they in turn be creolized? Are all cultural models creolizable to the same extent?

The Origin of the Concept

As Bolland (1998) explains, the concept of creolization has meant many things to many people over many centuries. The term is derived from 'creole' itself derived from Spanish 'criollo' which referred to (1) Europeans born in the islands during colonization (thus Joséphine de Beauharnais, the wife of emperor Napoléon, was called a 'creole' as she was born in Martinique, and was not considered totally French anymore); (2) displaced people brought to the Caribbean and Indian Oceans and who contributed centrally to the local plantation economies; (3) the societies that developed during cultural contact in these places; and (4) an islander of mixed 'race.' The overarching theme of 'creole' and creolization thus, is that of transformation. Linguistics borrowed the concept from this social history, but it is worth noting that the concept of creolization appears as early as 1884 in the work of de Quatrefages, a French ethnologist who borrowed it from a letter received from M. Levy (Benoist, 2013: 20). In Linguistics, creolization refers (1) to a process of transformation of a pidgin language into the main language (and often, into the mother tongue) of a new linguistic community, and (2) to the creation of a creole

language out of different languages (at least two) without an intermediate pidgin state (*see* Pidgin and Creole Language Varieties). It is this second meaning that has been adopted by anthropology. A pidgin or a creole developed as a response to communication pressures, in situations of intense cultural contact and often hegemonical conditions such as those found on colonial plantations of the New World, where people from different cultural origins and who spoke mutually unintelligible languages developed a new common language. Human agency and asymmetrical power relationships are central to the creation of these languages. Pidgins and creoles incorporate features from languages available to the pidgin/creole makers: the new language is distinct from the languages that shaped it, yet it often retains a sufficient number of their features, that its origin can be traced and identified. Theories of pidgin and creole genesis are highly debated in creole studies, yet scholars agree that the characteristics of pidgin and creole languages include the (1) speed with which they form and develop; (2) the sociological conditions that have shaped their development, most typically, European colonization, and in some geographical areas such as the Caribbean, the Indian Ocean and the Western Pacific, plantations economies; and (3) an almost instantaneous and continuous creativity. In many instances, creoles coexist with their lexifiers (typically, the colonial language that served as the source of the bulk of the lexicon) and regularly suffer from negative comparisons with them. Purist linguistic ideologies denigrate the hybrid nature of creoles, their supposed lack of syntax, and most of all, their lack of written literature.

Creolization and Anthropology

Despite the epistemological difficulties inherent to the transfer of theories and analytical models across disciplines, the concept of creolization seems to have captured the imagination of some scholars as a way of talking about and analyzing rapid cultural change associated with contact between societies of different ideological and technological orientations.

One wonders why the concept of creolization was applied to these phenomena when the more technically appropriate concept of 'pidginization' was available (see Jourdan, 1987; McKellin, 1991). Knörr (2010) proposed that pidginization would have been more appropriate as the term speaks to the development of common cultural elements amid cultural diversity, whereas the process of creolization entails indigenization that is not always a result of cultural contact. I suspect that the choice of creolization over pidginization is linked to two factors: first, the word 'creole' already existed in social sciences and public discourse to refer to the people and plantation societies of the Caribbean and the Indian Ocean. In these societies, typically characterized by a high degree of cultural diversity and intense contact, creolization took place with the building of communities and the development of indigenization. In other pidgin/creole speaking societies, that was not the case. Intense cultural contacts between different ethnic groups did not erase ethnic differences, but led to the development of new cultural formations. Second, for a long time pidginization has been thought of as a process of linguistic impoverishment, whereas creolization was always associated with linguistic enrichment. Using the former label could have been seen as a pejorative and inadequate label to describe a process of cultural creativity where 'loss' had no place.

The metaphorical power of the concept of creolization, particularly with the implication it carried that new ways of being in the world and living together appeared, made it preferable to the more technically correct pidginization. The earlier examples of such usage appear in the works of Drummond (1980), and Hannerz (1987). In parallel, French linguists, anthropologists, and literary critics, working in West Africa, in the Caribbean, and in the Indian and Pacific Ocean developed other concepts to discuss similar phenomena: *créolité* (Mannessy, 1987; Chaudenson, 1992; Bernabé et al., 1989); creolicity (Jourdan, 1985) and, of cultural *métissage* (Amselle, 1990).

In contemporary social sciences, creolization is being used in different ways, with more or less attention paid to history and power relations between peoples and cultural groups, and greater and lesser claims on recognizing the heuristic dimension of the concept. A first approach uses creolization as a concept that refers to processes of 'transculturation' leading to nativization. It is argued that the concept of creolization is most useful when restricted to those social transformations that take place under the hegemonical conditions of colonization, to the relationship of power and inequality that characterized the prevalent social conditions of colonization, and to the processes of 'transculturation' leading to indigenization during colonial times in the Caribbean and the Indian Ocean. Shih and Lionnet (2011: 31–32) argue that this '*geohistorical specificity*' warrants the restriction of the concept to these areas. But as Stewart (2007: 5) asks "*Can the Caribbean exercise copyright over the meaning of creolization?*" An extension of this restriction is *créolité*, the French Caribbean intellectual movement analyzed in the work of Bernabé et al. (1989). *Créolité* puts an emphasis on identity and serves as a conduit to more ideological considerations of nation-state building and nationalism (see Tauchnitz, 2014). While some authors claim that the use of creolization is appropriate only in such societies (Chaudenson, 1992), others, such as Stuart Hall (2003) and Françoise Vergès (2007), argue that creolization cannot be dissociated from the power relationships that framed it. Thus creolization is not simply a process of social change; it is a process of social change that entails "*inequality, hierarchization, issues of domination and subalternity, mastery and servitude, control and resistance*" (Hall, 2003: 31, cited by Shih and Lionnet, 2011: 25). Using it lightly as a metaphor, it is argued, would obfuscate these power relations and the forced transculturation that it entails (Shih and Lionnet, 2011). This approach stresses that creolization cannot be used as a 'master metaphor' for similar processes around the globe. Indeed, in his important review, Palmié (2006, 2007) warns against the danger of appropriation of the concept by different fields without consideration for its original historical, social, and geographic context.

A second approach uses creolization as a metaphor for capturing elusive processes of integration of new cultural forms, associated with globalization. Used in that way, the meaning of creolization remains very akin to that of hybridization and creates the same type of conceptual ambiguities: is it the process, or is it the results of structural modification or reorganization? The image that there is something that gets

mixed with something else to produce yet another thing (e.g., the new form of marriage in Honiara mentioned above), is inherent to the metaphor. As such, it is an interesting shortcut into the description of phenomena not easily definable, but which seem to be clearly associated with the complexification of social relationships. Creolization, in that sense, is used to refer to a recombination of structures, practices, and meanings: a case of 'new wine in old bottles' or 'old wine in new bottles.' Used only as a metaphor, creolization (and hybridity) fails to explain how these kinds of phenomena warrant the usage of this new term rather than intersystem (Drummond, 1980), syncretism (*see* Syncretism), bricolage, or métissage, those other concepts central to a study of social change that focuses on the in-between. In as much as they focus on the dynamic intermixing and restructuring of meanings, both concepts are similar. Both capture the image of the in-between, the neither/nor, flux, and vanishing boundaries. But while 'hybridity' and 'métisse' focus on the result (Benoist, 1996; Chanson, 2011; Tauchnitz, 2014 for important reviews of these concepts), creolization focuses on the process.

But what process? If the concept is going to be analytical rather than remain epigrammatic, as Stewart (2007) claims it is, it ought to cover a precise semantic field. As he says, "*the term 'creole' has itself creolized, which is what happens to all productive words with long histories*" (2007: 5). But can we be satisfied with using a term whose meaning gets bleached by usage over a short period and is becoming more polysemic with time? Metaphors are not devoid of reality. They are anchored in it. Though creolization implies cultural creativity, its ebullience is not synonymous with chaos; and though it certainly leads to new meaning making systems and new knowledge systems, one cannot be satisfied with defining it solely as an aesthetic movement, or an exercise in identity creation or affirmation, or a metaphor for quick social change. One must find its inner workings, but one should not limit it to expressive interaction. To put emphasis solely on the folkloric dimension of creolization (see Baron and Cara, 2011 for a discussion) is to miss out on its power to evoke the cultural restructuring that is at the basis of the cultural creation that Mintz (1996) writes about. Are we being well served by claiming that creolization is simply a creative, chaotic, and playful response to cultural contact, akin to bricolage? No. Creolization is not some form of *angélisme*, nor is it a form of chaos.

A third approach uses creolization as an analytical model for the study of social change drawing on an analogy with the linguistic model of creolization–pidginization described above. This is a stronger reading of the concept of creolization: It proposes ways of identifying the cultural logic which provides answers to the following nagging questions: What changes and what does not, and under which conditions? What is the nature and the pace of the change? If culture is practice and not simply ideology, how does change affect this practice? If culture is text, is every aspect of culture affected in the same manner and to the same extent? If culture is grammar, are there parameters and constraints for change? What makes the change acceptable? This version of creolization rests on a set of assumptions about the deep grammatical nature of cultural engagement: (1) that moral-existential aspects of culture can be differentiated from instrumental aspects; (2) that the latter change at a faster pace than the former; and (3) that, with regards to the pace of change, they can be compared with the syntax and lexicon of a language respectively. In situations of nascent creolization, local instrumental aspects of culture are often replaced, along with their attending symbols and meanings, with those from another source. The moral-existential aspects of culture are now sustained by new symbols, and may be given slightly different meanings, but will still be perceived as essential to the group's definition of identity (Jourdan, 1987; Mercer, 1988 cited by Stewart, 2007: 6). The bridewealth payment mentioned above is essential to the father's standing in one of his networks (here his lineage) and justifies his traveling back to the home village to collect it. All participants in the transaction agree that the meaning of such bridewealth is now very different from what it used to be, and that the amount is inflated. Yet bridewealth has to be paid, even against the wishes of the parish priest, because this form of exchange is essential to the integration of lineages, and therefore to the father's identity as a member of the group. Critics of this third approach, Briggs (2002) and Palmié (2006, 2007) argue that linguistic theory should not be used as a foolproof mechanism to understand social processes, even more so because the very theories that buttress this approach keep changing. But if creolization is invoked loosely, and if it not to be heuristic, what is its usefulness? As with any form of social process, creolization rests on people's understandings of how they wish to or have to engage the world. It is associated with a reconfiguration of self and of the practice of identity. Undoubtedly, there is a distinct advantage in identifying the processes that lead to a redefinition of people's practice of identity, even if, initially, this identification may start with an analysis of the features and elements that are being transferred across cultures, with or without attendant localization.

Essentialism

Some critics of creolization theory have argued that it is essentialist because it presupposes the existence of pristine cultures that will subsequently join, mix, overlap, and be reshaped (Friedman, 1994). Proponents of creolization reject this notion, and point to culture as a locus of permanent change, made even more spectacular at particular times in the history of societies. They also point to the shortcomings of a conception of culture as a bounded pristine entity. Creolization stresses the importance of the negotiation of meaning and shows that the 'vivre-ensemble' is engaged with and not simply lived-in. If creolization were an essentialist theory, the concept of cultural loss would be integral to its definition. Yet, it is not, for the simple reason that talking about loss in connection with social change implies a move away from the ideal, but unreal, pristine state of tradition. Loss belongs to a theoretical framework in which cultures are seen as essential wholes, neatly bounded self-reproducing structures, impervious to the passage of time, and deriving legitimacy from a primal pristine state. Cultures are no less authentic because they are creolizing. The new cultural practices, and the new cultural forms, that have emerged out of the creolization process are not any more authentic or spurious

than the ones they are derived from, or more spurious or authentic than societies that have changed in other ways. They simply exist. What is revealed by the creolization concept is the endless negotiation of meaning that takes place when groups and individuals engage in social relations within societies. The pace and scope of these cultural negotiations are more important in situations of rapid social change. The strength of creolization theory is that it points to (or foregrounds) elements that are not easily captured by other models: heterogeneity rather than homogeneity, process rather than stasis, fragmentation rather than integration, multiple rather than singular identities, multiplicity of voices, continuity of movement. Above all, it points to the domain of culture as contested ground rather than public space.

The World System and Globalization

Typically, but not exclusively (see Hannerz, 1996) the creolization concept has been applied to the analysis of social change in the so-called Third and Fourth World societies, in colonial and postcolonial situations. Colonial, postcolonial, and hegemonical contact relations are particular in the type and speed of the sociocultural change they provoke, and are best suited to be studied with the paradigm of creolization that includes the speed of change as a defining element. Critics have argued that the quasi-exclusive application of creolization theory to these societies represents them as powerless and reinforces the *fait accompli* of colonization by strengthening stereotypes. The argument is usually framed in relation to the World System theory and to the concepts of core and periphery. There may be a reason for this affinity: the very sociocultural formations and ideologies that have fostered the development of creole languages have reappeared under a new guise, that of the World System, economic and cultural, which creates even more pressures for change in these societies than anywhere else at the same moment. These types of contact-induced ideological and experiential pressures resemble the superstrate and substrate influences at work in the formation of creole languages, in that they juxtapose and confront practices and meanings that are produced by different social systems and ideologies. This raises the question of the relationship of creolization to globalization. Creolization shares with globalization an increase in available modes of social organization and cultural representation (Pieterse, 1995), both offer more options. Both are associated with more culture and not less, even if, on the surface, things look different. But with globalization residing in a movement of ideas, as much as in people's engagement with new sets of ideologies and practices, one could identity, as Hannerz does in Stockholm (1996), creolizing formations in nontypical creolization sites.

Creolization and Fast Social Change

It is in cities that creolization is the most obvious, if only because of the rate and scope of change. As cultural market places, cities are the loci of very fast sociocultural mutations that lead some observers to talk of acculturation and deculturation, and not only of adaptation to an urban way of life. Creolization is neither. When full-fledged towns and cities develop over a mere 50-year period, as is the case in many parts of the Third World, in places where there is no local tradition of urbanization, for instance, it requires on the part of urbanites a reassessment of the parameters of their identity (as with the father's behavior at the time of his daughter's wedding) and subsequent engagement in new types of social relations of the type and scale that is not found in other forms of sociocultural change. What is typical of cities is the ebullience of cultural creativity. Only a close study of the superstrate and substrate influences could reveal why, despite the onslaught of a generic cultural and economic World System (the superstrate) onto local traditions (the substrate), the cultural formations of urban Nigeria (Hannerz, 1987), Solomon Islands (Jourdan, 1985), and Guyana (Drummond, 1980) are similar in very many ways, and yet very different from one another. This begs the question of the specificity of creolized societies: Are they any different from other types of societies, given the fact that all societies are changing, and that many contemporary non-Third World societies have, at some point in their history, lived in situations of colonization, invasion, or hegemony? Maybe they are, if only because of the speed and the depth of change that characterize them, and give the impression of a permanent flux.

Final questions remain. Will the concept prove more useful when applied to some social contexts of change and not to others, defined geographically and historically? Will anthropology be better served by using creolization as a universal synonym for fast cultural change associated with globalization and characterized by the blending of forms, meanings, knowledge systems, and structures? Will it be better served if creolization proves a heuristic concept that goes beyond the metaphor but helps understand and describe contemporary processes of change and mixing in light of increasing cultural complexity?

Abstract

To assess the importance of social class in the production of some kinds of crime, we define social class and discuss the many kinds of conduct called crime. After a review of theoretical approaches to class and crime, we examine major research approaches to the issue, starting with studies of business cycles, unemployment rates, prisoner characteristics, and their relationship to crime rates. We then review studies of the distribution of crime rates in geographic areas, studies based on victim and self-report surveys, and close with a promising new approach, the creation and analysis of official registries.

A Basic Question

In 2001 Uggen asked, "Does social class affect criminal behavior?," and pointed out that criminologists have wondered about the importance of social class in the production of some kinds of crime for over a century. The lack of consensus on the issue is due, in part, to differences in the definition and measurement of crime and in part to disagreement about the meaning and measurement of social class. Social class usually refers to the social and economic status of individuals or families, but in criminological discussions it more often suggests a set of categories used to classify victims or offenders based on their wealth and income. There are discussions of values and culture, such as 'middle-class values' and 'lower class culture,' but most treatments of crime and class use occupation, employment, or education as indicators of income and wealth. In general, assessments of the social class of individuals or groups of individuals in criminology have been based on personal or family income, unemployment, education, occupation, or parent's occupation or education. At times combinations of these measures have been used. In general, the social class categories used in discussions of crime and class have been broad and sometimes vague, and there have been good reasons for this. We can say in a general way that those who own a great deal of property and have high incomes are rich or upper class and those who own less or nothing and have low incomes are poor or lower class, but beyond this general notion the issue is quickly complicated. No commonly accepted set of classes exists.

Changing definitions of crime have complicated the issue as well. Conduct officially defined as crime is usually the result of a legislative process, but in practice crime is defined by administrative policies and enforcement procedures. This can be seen most easily when considering crimes such as drug possession, gambling, and prostitution. In such cases, there is generally no identifiable victim and thus no complaining witness. The number of arrests and prosecutions will depend on enforcement policies and practices rather than calls to the police. Since those arrested and incarcerated for such offenses are disproportionately people with low incomes, limited education, and histories of unemployment, a link between class and crime is a plausible conclusion as is bias in the operation of the system of justice. The relationship is less obvious when assaults and thefts, crimes clearly involving direct victimization, are considered.

However, definitions of crime also were complicated by criminologists in the 1940s and 1950s when they started to ask young people to report their own illegal or improper behavior. In some of the early self-report studies so much youthful conduct was defined as delinquent that almost any child could be said to have committed a delinquent act, and this weakened the link between class and crime. Moreover, the early self-report studies did not develop a uniform or standard self-report format, and this, combined with the use of different social class measures, produced conflicting conclusions about the importance of social class as a predictor of crime.

Prior to the widespread use of self-report studies, the link between class and crime was studied by looking at the possible impact of economic conditions on crime rates, asking if economic downturns are followed by higher crime rates, and focusing on the social class of prisoners. By the 1930s, comparing crime rates for specific geographic areas with the social and economic characteristics of the areas was added to this set. Such studies asked if areas with indicators of high-poverty rates and low-social class were also areas with high-crime rates. The answers produced by these older approaches probably influenced the development of theories attempting to explain the reasons for the crime and class relationships. A brief history of important theoretical perspectives on social class and crime is presented below, followed by a review of the research tradition on this topic. Both discussions should highlight important definitional and measurement issues.

Class and Crime: The Theoretical Tradition

Prominent twentieth-century criminologists generally accepted the suggestion that class or some approximation of it was important in the generation of many forms of crime. Shaw and McKay found that crime and delinquency were linked, at least geographically, to low income, unemployment, dilapidated housing, and a lack of neighborhood organization. In addition, Shaw's use of life histories, presented by some young delinquents, provided detailed accounts of ways in which

impoverished areas provided young people with criminal opportunities. Their theory tried to explain why some area characteristics produced higher delinquency referral rates.

Robert Merton set out to explain why criminal conduct was so often an activity of poor people. His explanation is so plausible that some have wondered why it was not presented sooner. He suggests that almost all Americans come to believe that the primary goal in life is the achievement of monetary success and, at the same time, learn that there are culturally prescribed rules for doing this. More importantly, he argued that the economic position of some people effectively eliminates the possibility that they will achieve monetary success if they follow the rules and that this causes some individuals to increase their income by ignoring the rules. His discussion is more complex than this, but it provides an explicitly structural explanation for much crime and suggests that affluent individuals will commit less crime than poor people. Edwin Sutherland developed a more complex social psychological theory suggesting that individuals learn to accept or reject beliefs conducive to or hostile to criminal conduct based on the views of those with whom they associate and depending on the strength and priority of those contacts. However, he also introduced an activity he called 'white collar crime' in which crime is not committed by the poor but is engaged in by high-status individuals in connection with their occupations. From this perspective, asking about the impact of class position on specific types of crime may be more useful than asking whether social class position affects criminal conduct in general.

The gap between Merton's and Sutherland's approaches is not as wide as it seems, if we focus on Merton's suggestion that when people find themselves unable to achieve monetary success, if they follow the rules, one option is to innovate and break the rules. However, even people with large incomes and great wealth may want to increase their wealth and the status that comes with it. If they find their ability to do this limited by rules regarding financial transactions, they too may innovate and break the rules. Therefore, by viewing the differences between the illegal conduct of lower class people and the illegal conduct of upper class people as a matter of scale, it is still possible to attribute some crime to the impact of institutional constraints on conduct in the face of culturally prescribed goals. That is, it is still possible to see illegal conduct in structural terms. To be sure, the link between social class and crime is different in those rare cases when high-status people commit high-level financial crimes. We describe these crimes as rare because only a small percentage of the population find themselves in positions that allow them to steal very large sums of money. This suggests that high status can lead to crime but that, for people at the bottom, class and crime are linked because their position in the economic system limits their ability to succeed financially if they follow the rules.

Cloward and Ohlin suggested a different way to bridge the theories of Merton and Sutherland by focusing on the importance of opportunity in a variety of forms. However, they too assumed that the lack of economic opportunity, legal or illegal, was an important contributor to much criminal conduct. Like Cloward and Ohlin, Albert Cohen used ideas form Merton and Sutherland to explain the conduct of lower class boys in urban areas. He relied heavily on material from Shaw's life histories, for examples of delinquent conduct, and his book is notable for its careful description of the behavior to be explained. Cohen suggested that many lower class boys engage in delinquent conduct, in part, because of their desire to be accepted by teachers and other middle-class adults and by their lack of qualities that middle-class people admire. His argument is more nuanced but he assumes that much if not most urban, male, gang delinquency is lower class in origin. In a critique of Cohen's approach, Walter Miller suggested that it was lower class culture itself that created higher rates of misconduct among lower class boys. His conclusions were based on the comments of gang workers about the basic concerns of lower class children and their parents. Gang workers were people trained to locate, work with, and try to redirect the activities of urban gangs. Neither Cohen's nor Miller's theory generated a research tradition, but both may have inspired other theories of crime.

Walter Reckless was intrigued by the fact that some boys in high-delinquency areas did not engage in delinquency and developed what he called a containment theory to explain it. Basically, he suggested crime is the result of the failure of internal and external controls of conduct. At about the same time Short and Nye modified a technique for studying delinquency by asking young people to answer questions about their own misconduct. Because such self-reported delinquency studies frequently used questions about parental occupation and education many of the early uses of this procedure suggested a much weaker link between class and crime than earlier approaches. The self-report approach encouraged the use of questions about the child's relationship to parents and teachers and allowed the children involved to give some indication of their feeling about rules of conduct in general.

Perhaps the most salient theory to come out of this approach is the version of social control theory, which Travis Hirschi presented in 1969 in his book, *Causes of Delinquency*. His version of the theory proposes that it is attachment to teachers and parents, involvement in conventional activities, belief in the validity of rules, and fear of punishment that prevents boys from engaging in some forms of delinquent conduct. Later versions of the theory suggested that these factors or closely related factors had more to do with involvement in criminal conduct than class position or class origin.

Class and Crime: The Research Tradition

The Business Cycle, Unemployment, and Prisoner Characteristics

Although Bonger focused on the impact of economic conditions on crime early in the twentieth century, studies of the linkage between economic cycles and crime have been relatively rare. However, a 2006 study of business cycles and street crime compared trends in the 'Gross State Product' with changes in state-level robbery and property crime rates from 1980 to 2000. The authors concluded "that an improving economy has a negative and statistically significant effect on all four … property crimes and robbery" (Arvanites and Defina, 2006). In addition, there have been numerous studies of unemployment and crime. Ted Chiricos in a review of 63 such studies reported a consistent and positive relationship between unemployment and crime (1987), and a review of articles

published later found a relationship between unemployment and property but not violent crime.

Other early studies looked at the social class of prisoners and found that convicts were generally poor. In this tradition, a 1991 survey of state prison inmates in the United States found that, prior to their most recent arrest, only one-third of the prisoners had completed high school, one-third of them were unemployed for the month before they were arrested, and only about half of them reported annual incomes of $10 000 or more (U.S. Department of Justice, 1993). In addition, the Bureau of Justice Statistics report on the characteristics of the inmates interviewed in 1991 noted that they were mostly male (95%), minority (65% black or Hispanic or other race), and young (68% were under 35). Interviews of prisoners in state prisons that were conducted in 2004, indicated that only 40% had completed high school, 30% were unemployed for the month before they were arrested, and only 52% of them reported annual incomes $14 000 or more (National Archive of Criminal Justice Data).

Social Area Analysis

When Shaw and McKay developed Social Disorganization theory they were trying to explain why most children referred to the Cook County Juvenile Court during the first quarter of the twentieth century lived in economically disadvantaged areas of Chicago. Their Social Disorganization theory grew out of a systematic comparison of referral rates with the social and economic characteristics of geographic areas in Chicago from 1900 through the 1930s (Shaw and McKay, 1969). Although Shaw supplemented the statistical analyses with a series of life histories of children referred to the court, his work with McKay remains one of the best examples of the use of factual information in the study of crime and delinquency. Their work, and the work of others who repeated the process for different cities in the 1950s, 1960, and 1970s, clearly suggests that delinquency referral is related to social class.

However, in 1962 Karl Schuessler altered the approach by using the characteristics of 105 cities rather than the characteristics of neighborhoods to examine the correlates of specific crime rates for 1950. One of his basic findings was that "specific offenses may be combined into broader categories, but that a single, composite index of crime would be of doubtful value." Another was that the percent of the population engaged in manufacturing contributed most heavily to variations in crime rates. Where manufacturing was high, all seven offense rates were low. Then using a correlation technique designed to indicate whether or not a small number of factors might explain the variation in crime rates for these cities, he found that one important general factor might be called 'income and race,' and a second factor could be labeled 'education and manufacturing.' His general conclusion was that the incidence of crime is a function of a city's social and economic characteristics.

Between 1960 and 1990, a number of studies of the correlates of crime were conducted. Some investigators used the delinquency rates for census tracts and others used city-level, county-level, or state-level rates. The variable to be explained in these studies was sometimes an overall crime rate reflecting UCR counts of violent and property crimes. In other cases, researchers focused on homicide or robbery. Homicide was a frequent choice because it is the most serious crime in the UCR set and because it is believed to be accurately reported. The creation of the Supplementary Homicide Report program in the late 1970s may have drawn additional attention to homicide. This made it possible for Land and his colleagues to review the published results of 21 studies that looked at the social and economic correlates of homicide. Some of the studies looked at the homicide rates for U.S. cities, some used metropolitan area rates, and some used state rates. Some of the studies used 1960 data, some 1970, and some 1980 data. Land et al. found great inconsistency in the results produced by the earlier studies and set out to create a standard set of variables that could be used in the same way for each period for a set of cities, a set of metropolitan areas, and all 50 U.S. states.

However, the major change they introduced in their own analysis was to use a new variable created by combining a set of highly inter-correlated variables and calling it a 'resource deprivation/affluence' component. The variables used were 'percent black,' 'percent of children not living with both parents' (essentially 'mother–child families'), and three income measures. The variables most highly correlated with the overall homicide rate for all four periods were percent black, mother–child families, and percent in poverty. The new composite variable appeared to be a way to deal with the interconnections of these three variables, but one impact was to draw attention away from attempts to understand the role of family structure and racial composition in the production of high homicide rates.

To avoid this blind spot, some criminologists started analyzing black and white crime rates separately. Peterson and Krivo found that residential racial segregation was a strong and significant predictor of high-black homicide rates and that the percent of black residents in professional and managerial occupations predicted a lower black crime rate (1993). Parker and McCall found that economic deprivation affects the within-race homicide rates for white and black city residents (1999). Earlier, Sampson found that black male unemployment contributed to an increase in black mother–child families and that mother–child families contributed to high homicide and robbery rates (1987).

In 2009 and 2010, a group of criminologists returned to the questions raised in the 1990 Land et al. study to see what had changed since 1990. In a version presented at a 2009 Annual American Society of Criminology (ASC) meeting, the authors introduced additional variables and removed percent black from the deprivation/affluence measure, using it with percent foreign born to create a 'heterogeneity' variable (McCall et al., 2009). They reported that their analysis suggested that the 'resource deprivation/affluence' component, even without percent black, was a statistically significant and positive predictor of the overall homicide victim rate. However, in the published version of the paper, when percent black was put back in the deprivation component and the segregation measure was not used, the deprivation component was positive and statistically significant for all four time periods (McCall et al., 2010). The standardized coefficients for this version indicated that deprivation was the strongest predictor of the homicide rate for all four analyses. Taken together, these studies of the correlates of urban crime rates provide support

for the suggestion that crime rates, especially violent crime rates, are higher for urban areas with large lower class populations than they are for areas with more affluent populations.

Victim and Self-Report Surveys

Two kinds of surveys provide estimates of the social class of victims and offenders. In victim surveys, respondents provide information about themselves and their families and answer questions about their experience as crime victims during the preceding 6 months. Reports of a 2005 victim survey in the United States suggested a violent crime victimization rate of 38 per 1000 households with incomes below $7500. This was twice as high as the crime rate for households with incomes of $75 000 or more. This 2:1 ratio was constant from 1993 to 2005, the last year that income information was published for violent victimizations. The pattern was different for property crime rates. For 1993, the property crime rate was 400 per 1000 households with incomes of $75 000 or more and 306 for households with incomes of less than $7500. However, the rates for these two income categories gradually changed so that by 2010, the property crime rate for households with low incomes was almost twice as high as the rate for high-income households. This suggests that by 2010, low-income respondents were more likely than high-income respondents to be victims of crime.

Surveys asking individuals to indicate how often they have engaged in criminal or delinquent conduct usually include questions about income and education. Those most often completing such surveys have been juveniles, so they were usually asked about the income and education of their parents. Self-reported crime surveys have not created a standard format, so the kinds of misconduct studied and the measures of social class used have been similar but varied. Nevertheless, a large number of self-reported delinquency studies have suggested a very weak relationship between social class and delinquency. A review of such studies led Tittle et al. to conclude that the class-crime link was a myth (1978). However, a comprehensive international review by Braithwaite, that included self-report studies, studies of social areas, and other research approaches, found that social class is a strong predictor of crime in the United States and around the world (1981).

A self-report survey conducted in Greece, Russia, and Ukraine in 2006 asked adults about their criminal and deviant conduct. The use of adults was an important break with the traditional use of juveniles. Believing that questions about education or occupation in these countries would not be accurate measures of social class, the investigators used questions asking respondents if they could afford food, clothing, housing, medicine, and travel to classify them by social class. The number of 'yes' answers to these questions indicated their class. Greek respondents with high-social class scores reported fewer crimes than those with low-social class scored, but Russian and Ukraine respondents with high-social class scores reported committing more crime than those with low scores. It is hard to say whether it was the use of adults, the use of 'telling a lie' as part of the crime and deviance measure, or the use of a new measure of social class that produced these interesting results suggesting that in some countries, crime is predicted by high income.

A Promising Approach

The advantage of self-report studies is that they do not depend on the police to provide the crime information they collect. The disadvantage of the approach is that key information provided by the respondents cannot be verified or corrected. However, another survey approach being used in several European countries begins with a large representative set of individuals that is supplemented by arrest information. A 2012 study of male violence in Finland compiled income, education, and unemployment information from 'several different administrative registers' for over 48 000 men born in Finland. This file was then expanded to include police information about arrests for violence of men in the file. Analysis of the expanded registry indicated that reports of violence were strongly associated with low socioeconomic status and a prior criminal record. Education, across all ages was the strongest predictor of all types of violence, while income and unemployment presented a weaker relationship for young offenders (Aaltonen et al., 2012). This approach may replace or drastically alter victim and offender surveys because it reduces or avoids problems of missing data caused by the unwillingness of some respondents to answer questions about income, education, and employment.

In the United States, it would be possible for four federal agencies, working together, to create a registry that would contain income, employment, occupation, and arrest information for a representative set of residents. The Census Bureau's American Community Survey already collects much of the nonarrest information needed, but with the cooperation of the Social Security Administration and the Internal Revenue Service the income and employment information could be augmented. After arrests in the FBI's Records of Arrest and Prosecution file are added, the registry would provide a very good indication of the linkages of social class with 43 different offenses. While such an approach is technically possible, it is not currently feasible because of laws prohibiting data exchanges among these federal agencies. Nevertheless, this is a promising approach that may eventually be adopted as more European countries develop such registries.

Overview

The role of social class in the production of some kinds of crime is important because of its implication for crime reduction. If rates of serious crime can be reduced by moving more people out of poverty, programs that work in this direction make practical sense. The addition of empirical support to ethical and political arguments for creating a more equal society might produce beneficial changes in many communities. This review of the evidence for a class crime linkage and its theoretical synthesis suggests that social class is important in the production of serious crime. The unemployment and business cycle studies, the Bureau of Justice Statistics victim and prisoner surveys, and the social area analyses almost all suggest this conclusion.

The evidence supporting the opposite conclusion is limited but strong enough to explain why there is a lack of consensus among criminologists. One issue that must be resolved to arrive at a more definitive conclusion is the impact of age on

self-report studies. When self-report approaches are used, it will be important for the surveys to include people other than juveniles and young adults. A second impediment to consensus is the wide variety of types of crime that can be studied. Focusing on crimes that can only be carried out by high-status people will indicate that one need not be poor to break the law, but it will not tell us much more about the crime and class relationship. A third impediment to consensus is the fact that criminology is data starved. Data about the income and assets of individuals that is linked to the criminal activity of the same individuals is quite limited. Moreover, some measures of crime, such as offenses known to the police, are simply measures of victimization, and none of the large-scale reporting programs, except the National Prisoner Survey, have information on the social class of offenders.

The issue may be complicated by the fact that crime and the response to it may have impact on an individual's life chances. That is, crime may impact social class in addition to social class impacting crime. Sampson and Laub's 1993 study of boys sent to prison for juvenile offenses suggests that being incarcerated at an age when other young men are finding work and starting families may have had an impact on their economic status in the years following incarceration. In addition, as we have seen, the class-crime link is certainly different for different kinds of crime. However, the crime and class issue is important in spite of the complications and difficulties in assessing the impact of class. As Hagan noted in his 1991 ASC Presidential address, "the simple omission of class from the study of crime would impoverish criminology."

Crime and Criminal Justice: Applied Research from Routine Monitoring to Evidence-Based Practices

Roberto Hugh Potter and Gail S Humiston, University of Central Florida, Orlando, FL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Applied research has been at, and remains at, the heart of the fields of criminology and criminal justice since the days of the 'moral statisticians.' This article examines some of the history of applied research in these fields, and the roles of government, university-based, and nonuniversity-based researchers. The impact of different sources of funding and the challenges that funding produce to the integrity of applied research are canvassed. Particular attention is paid to applied research in the areas of prevention, intervention, and evaluation studies. The development of evidence-based practices, implementation research, and translational research is also covered as part of the evolution of applied research in criminal justice and criminology. Exemplars in the areas of corrections and policing are offered to highlight the continuing development of this important aspect of the application of social science research to applied problems.

Applied research in criminology and criminal/juvenile justice can be traced back to the foundations of modern social sciences. The work of the 'moral statisticians,' such as Quetelet, often dealt with aspects of crime (Akers et al., 2013). The 1925 work on delinquency prevention and treatment by Burt (Lodge, 1974) in the United Kingdom and the Cambridge–Somerville (Glueck and Glueck, 1959) research in the United States provide examples of research undertaken by academics to address the problem of juvenile delinquency.

Our definition of applied research follows the tradition set forward by Kurt Lewin (1946), and reflected in Nettler's (1984) formulation of description, risk assessment, program evaluation, and explanation in criminal justice research (see also Potter and Krider, 2000). Likewise, the development of program evaluation methods and research projects plays a strong role in our approach here (Rossi et al., 1999).

There are three themes in the applied research worlds of criminology and criminal justice since World War II: corrections, prevention, and evaluation. As we will explore below, much of the early program evaluation was applied to the results of correctional interventions. Prevention programs and the three levels of prevention (primary, secondary, tertiary) were introduced to the justice fields in the mid-1970s (Brantingham and Faust, 1976), and the evaluation of those programs provided one more impetus to applied research. These themes have now led to the development of 'implementation research' (Fixsen et al., 2005; Taxman and Belenko, 2012), and the broader 'translational research' (e.g., Neyroud and Weisburd, 2014).

The development of applied research in these fields has been uneven, however. In this section, we will examine some of the influences of government monitoring, policies, and funding on criminal justice and criminological applied research. We will also examine the changing roles of the academic, government, and private sectors in the provision of applied research. Then, we will consider one researcher's work which forged an intellectual fork in the road, altering the course of criminal justice policies and research, carving new pathways. Finally, we will examine current applied research in corrections and policing, and the potential for future directions of untapped information on issues of criminal justice personnel. In the end, we hope to provide the reader with an understanding of how far we have come and how far we might be able to push applied research in this area of social control.

Is Crime Monitoring Applied Research?

One of the distinctions that might be made when discussing applied research in criminal justice and criminology is that between crime monitoring (or surveillance), especially 'passive surveillance,' and more theory-driven research. By 'monitoring,' we mean the systematic collection of data about crime events that can be utilized to describe the incidence of crime and allow the data to be utilized for attempts to predict and control crime (Potter and Krider, 2000). Unlike crime monitoring research, theory-driven research purposefully manipulates variables to observe an impact on a crime-related outcome.

Monitoring crime has been a long-term endeavor of many national governments. The French began systematic collection of criminal court data in the 1820s, and continue to the present, while the Uniform Crime Report (UCR) provides an exemplar of one of the oldest surveillance systems in the United States. For our purposes here, it is enough to point out that the UCR was developed in the late 1920s and published annually by the Federal Bureau of Investigation (FBI) since 1930. The UK Home Office began publishing official crime data in the 1950s, and Australia in the 1960s (Mukherjee, 1986). Although some may not consider these crime monitoring systems and their reporting to be research, without these efforts national- and international-level crime information would be even more fragmented than it is to date.

In the United States, the analysts at the FBI generally report only the basic observations and trends across time. They leave it for others to utilize the data for exploratory and theory-driven research purposes (see Akers et al., 2013 for a discussion of surveillance and monitoring systems). We would argue that while some may not view crime monitoring as applied research, it does form the foundation for others to conduct

applied research on crime trends and their relationships to other social facts. This holds for monitoring systems on crimes, criminals, and victims, as well as statistics related to the formal organizations involved in the criminal justice process, such as police, corrections, and courts.

The Government Wants Answers!

The role of government funding in applied criminological/criminal justice research cannot be understated. Perhaps the first nation to invest formally in applied criminological research was the United Kingdom. The Criminal Justice Act of 1948 established the Home Office Research Unit, which authorized the expenditure of funds for criminological research (Lodge, 1974).

In the United States, the President's Commission on Law Enforcement and Administration of Justice (1965), and its landmark 1967 report *The Challenge of Crime in a Free Society* (USGPO, 1967), led to the establishment of the Law Enforcement Assistance Administration (LEAA). The LEAA program provided substantial funds for criminal justice-related research to universities and consulting agencies, as well as funds to state and local agencies for personnel and hardware (sometimes referred to disparagingly as 'toys for the boys').

In Australia, the Federal Parliament passed the *Criminology Research Act 1971* to establish the Australian Institute of Criminology and the Criminology Research Council (CRC). These federal-level agencies conducted in-house research and communicated that research to states, territories, and the public. The CRC also provided grants to universities, state agencies, and local organizations to provide research and program services, though the impact of that funding was being questioned into the early 1990s (Chappell and Wilson, 1993).

This government involvement in setting criminological/criminal justice research agendas through funding has not been without critics, of course. Potter remembers lively discussions in the United States of the perils of allowing government funding to set the criminological research agenda during the late 1970s and early 1980s. Similar concerns were noted in conference panels in Australia during the late 1980s. At the time, however, many of these doubts were general in nature and few seem to have been published.

More recently, the voices of concern have become more explicit. In the United Kingdom, several authors noted the influence of government policy on the types of applied research being conducted (e.g., Jefferson and Shapland, 1994; Jupp et al., 2000). In the United States, Chilton (2001) used part of his American Society of Criminology Presidential Address to argue that such peak bodies should be advising legislators on what areas of criminal justice deserved research funding. Likewise, Israel (2000) lamented the increasing pressure on Australian universities to achieve greater external funding for research purposes and the contradictory pressures such as demands placed on the independence and quality of criminological and criminal justice research. Geis et al. (1999) were among the few who expressed concern about the influence of private-sector funding on criminological research.

Contributions from private foundations continue to be overlooked in the funding of applied (and theoretical) research in criminal justice. Over the past few decades several philanthropic foundations have provided funding to university-, private-, and nongovernmental organizations (NGO)-based researchers to conduct applied research across a broad range of justice issues. Some of that funding has spun off research organizations listed below, while other funding has even begun to comingle with federal funds to push research into particular arenas. The MacArthur Foundation 'Models for Change' (MacArthur, n.d.) initiative, for example, seeks to move evidence-based juvenile justice reforms across the United States.

This previous discussion focused primarily on the concerns of academic-based researchers. Whether or not all research funding carries with its implicit cues from the funding agency, or is truly 'objective,' remains an empirical question. An additional question becomes, Is it only academics who do applied research in these areas, and do they have the same concerns?

Who Does Applied Criminal Justice/Criminological Research?

Probably all Western governments have some crime monitoring and applied research capacity at the federal/national government levels (e.g., National Crime Prevention Center, n.d.; National Institute of Justice, n.d.). In Australia, Canada, and the United States, most states or provinces also have units in various justice-related agencies that conduct applied research and monitoring of criminal justice trends and efforts (several are listed in the reference section). For example, most state-level correctional systems in the United States have some form of statistics and research unit that generates annual data and conducts evaluations of certain interventions. Some provide funds for university and other researchers to conduct contract applied research, though such funds are generally much smaller than those provided by federal governments.

A great deal of applied criminal justice research is conducted by university-based faculty around the world. Such projects range from small-scale evaluation and organizational studies, often conducted pro bono or for small sums of funding or publishable data alone, to large-scale multisite and multi-university collaborations attracting large sums of funding. Because there is no centralized repository of total funds paid for university-based criminal justice research, much less separated by applied versus theoretical, it is impossible to state the total value of such to the criminal justice world.

In the United States at least, the private research sector, both not-for-profit and for-profit, have been involved in applied criminal justice research from at least the LEAA days. The end of LEAA brought a temporary movement away from the corporate research sector as large accounting and consulting firms shed their social science researchers in the absence of government contracts. In the current environment, these private organizations may consist of small collaborations between university-based researchers. For example, the Jill Dando Institute of Crime Science at University College London (JDI, n.d.) is among the hybrid academic–private sector entrants into the area of applied research. Larger research organizations also exist, such as the privately owned Abt Associates (Abt, n.d.) and employee-owned Westat (Westat, n.d.).

A range of not-for-profits (NGOs) have also played a significant role in applied criminal justice research over the past century. In the United States, the National Council on Crime and Delinquency began conducting applied research shortly after its formation in 1907 (Krisberg et al., 2007; NCCD, n.d.) and continues to provide such services. The Vera Institute is now more than 50 years old and continues to play a major role in criminal justice applied research and policy development (Vera, n.d.). These nonprofits have been joined by a myriad of others over the past few decades, with newer entrants such as the Urban Institute (Urban Institute, n.d.), Research Triangle Institute (RTI, n.d.), and the Pew Center on the States (Pew Charitable Trusts, n.d.) playing increasingly important roles in applied research in criminal justice settings.

A Fork in the Road

National governments spent a great deal of public dollars to research solutions to crime and to increase efficiency in their criminal and juvenile justice systems from the late 1960s to the early 1980s. Then came a rude shock in the form of the 'nothing works' revelation attributed to Martinson (1974). Martinson's brief was fairly broad, to study the effectiveness of offender treatment programs. His 'bald summary' with regard to the impacts on recidivism was: "With few and isolated exceptions, the rehabilitative efforts that have been reported so far have had no appreciable effect on recidivism" (Martinson, 1974, p. 25). In the paragraph prior to that statement, however, he conditioned what was to follow by stating: "The use of even this one measure (recidivism) brings with it enough methodological complications to make clear reporting of the findings most difficult… so that it is hard to tell whether 'what works' for one kind of offender also works for others." Whether or not Martinson's statements amounted to 'nothing works,' they had the dual function of spurring a legislative landslide to execution and incarceration regimens, while at the same time sharpening the resolve of criminal justice researchers to determine what might work. On an aside, 40 years later, Durose et al. (2014) observed that post-release offending patterns in the majority of US states have not changed appreciably from observations made during Martinson's review. This is regardless of employing either a retributive or rehabilitative correctional intervention approach.

Moving to 'What Works' and Evidence-Based Practices

Throughout the 1980s it appeared that the 'nothing works' and retributive philosophies guided legislative funding of criminal justice and criminological research, especially in the United States. At the same time, criminal justice/criminological researchers around the world were engaged in applied research to determine effective practices. The search for 'evidence-based' programs which decisively achieve their intended outcomes, such as crime reduction, continues today. The remainder of this article will deal with exemplar strands of research on evidence-based programs and practices in the areas of policing and corrections.

Corrections

As a direct response to Martinson's (1974) critique, a broad range of researchers in the corrections area, especially in Canada, began to explore the characteristics of individuals, groups, and communities which may affect the likelihood that persons convicted of criminal acts would continue to offend. Empirical research has shown that certain characteristics, or 'criminogenic risk' factors, are associated with the increased likelihood of offending. As a result, 'front-end' assessments and 'back-end' interventions were developed at a new pace. These efforts continue to the present and impact the practices of corrections at every level (local, state/province, and national).

Research has culminated in meta-analyses of correctional interventions in adult and juvenile justice settings, which have provided a set of principles of risk for offending and the development of a range of interventions to address the dynamic risks (Andrews and Bonta, 2010; Farrington and Welsh, 2007; Lipsey, 1992; Lowenkamp et al., 2006; Smith et al., 2009). These have led to the development of the 'Risk-Need-Responsivity' (RNR) actuarial approach to assessing the dynamic criminogenic needs of offenders and to placing them into interventions appropriate to the need and individual offender's readiness for change (Andrews and Bonta, 2010).

The development of risk assessments and evidence-based interventions, as well as the subsequent RNR process, have led to a concern with what Gottfredson (1984) termed 'fidelity' and implementation. In Gottfredson's approach, fidelity had to do with the integrity of the intervention being implemented and moving into what we would now recognize as a form of continuous quality improvement. These ideas have been wrapped together into 'implementation science' (Fixsen et al., 2005; Taxman and Belenko, 2012). Implementation science suggests that we should treat the outcomes of interventions and implementation as being equally problematic and deserving of study. After all, if the notions of 'intervention' rely on fidelity of 'implementation,' then the two are inextricably linked in theory and practice.

As noted earlier, the lack of significant change in the proportion of prisoners who recidivate within 3 years of release from prison in the United States suggests we have a way to go before documenting the impact of our current assessment and intervention programs. Likewise, recidivism in Australia (Payne, 2007) and Canada (Nouwens et al., 1993; Bonta et al., 2003) remains stubborn. This is an area of applied research across risk, responsive interventions, and implementation, which is sure to continue as we seek ways to respond to those for whom prevention fails.

Law Enforcement/Policing

For most citizens, police are the most likely point of contact they will have with the criminal justice system. In terms of sheer numbers (though not necessarily budgets), police are the single largest segment of the criminal justice system. Because of the discretion afforded police officers, they are also the gatekeepers to the process. It is not difficult to see why so much applied research focuses on policing. This ranges from assessments of

technological innovation on police activity and effectiveness (e.g., Chan, 2001; Grossi, 2008; Terrell et al., 2008; Wolf and Gordon, 2007), to studies of organizational factors associated with effective policing (e.g., Lambert and Paoline, 2010), to citizens' perceptions of police legitimacy and impact on crime (e.g., Gau, 2013).

One exemplar of applied policing research that has spanned more than 20 years is the police response to domestic violence incidents (Sherman, 1992; Sherman and Flynn, 2014). The 'Minneapolis experiment' combined the gold standard experimental assignment of cases to arrest or no arrest, and recorded subsequent behaviors by the alleged offender to the nonarrested partner (and in other sites other victims). The results reported were varied in terms of reducing subsequent violent behaviors by those arrested. Yet, for many years, these experiments led to statutory and departmental policies that required the arrest of accused domestic offenders.

Recently, however, an analysis of follow-up data from one of the original sites (Milwaukee, WI), had shown that death rates were twice as high among African-American women whose partners were arrested during the experiment as compared to those African-American women whose partners were not arrested (Sherman and Flynn, 2014). While these deaths are not directly attributable to domestic violence or the arrested partner, they do raise questions about unintended outcomes from applied research – or, adverse events. The study of adverse events of our intended interventions is among those areas in which applied criminal justice researchers are lagging.

The entire area of 'intelligence-led' policing (Ratcliffe, 2008) is another evidence-based subject where decades of applied research have come together to inform crime prevention and intervention efforts at the local level. Employing an experimental design, Ratcliffe et al. (2011), demonstrated the impact of foot patrols aided by intelligence systems and analytics over automobile-based patrol activities in the city of Philadelphia. Along with the observed intended crime reduction outcomes, the researchers also noted public health interventions and positive outcomes achieved by police being closer to the public they served.

Personnel Matters!

One of the often overlooked areas of applied research in criminal justice involves personnel studies. Issues of personnel recruitment (Stinchcomb, 2008; Stinchcomb et al., 2006), selection, early warning systems (Walker et al., 2000), and retention are of great importance to criminal justice and allied organizations. While some of these are destined to be published in academic peer-reviewed outlets, many more are produced for individual agencies or peak organizations. The US National Institute of Corrections (www.nicic.gov) is one of the best repositories of such reports available. Just about every criminal justice sector will also have a professional magazine (e.g., *Police Chief*, *Corrections Today*, etc.) or professional association Web site (e.g., American Correctional Association, American Jail Association, etc.) where articles regarding applied studies of personnel issues are published.

Conclusion

This article provides a very brief overview of some areas of applied research in the criminal justice/criminology area. As noted earlier, such research is carried out regularly around the world by governments, university-based faculty researchers, and private-sector researchers. Much applied research is intended to address specific issues and problems faced by agencies, not necessarily for peer-reviewed articles and texts. The research skills and knowledge necessary to conduct applied research on behalf of agencies are the same as those required to produce 'scholarly' research. To paraphrase the old *Dragnet* opening, 'only the audience is changed' in most applied research. Rather than informing other academics, the purpose is first to inform decision makers at organizational levels.

In the end, applied research of all types still needs to be rigorous and ethical. How it is valued by the academic world and the applied world is often a contentious matter, especially when it does not undergo peer review. For the end consumers of the information, the rigor and the utility of the information for their interests will ultimately dictate the value of the work.

> The problems of crime bring us together. Even as we join in common action, we know there can be no instant victory. Ancient evils do not yield to easy conquest. We cannot limit our efforts to enemies we can see. We must, with equal resolve, seek out new knowledge, new techniques, and new understanding.

Abstract

Research consistently finds that females are much less likely than males to engage in illegal behavior. This article summarizes scholarship examining the relationship between gender and crime, which often follows one of three approaches: (1) Macro-level research examines national trends in women's offending compared to men's, emphasizing explanations for changes in the gender–crime gap over time. (2) Qualitative research on women's offending focuses on how social environments influence women's decisions to commit crime. And, (3) Individual-level analyses of survey data center on sociopsychological explanations of why males are more likely than females to break the law.

One of the strongest findings in the criminological literature is that there is a gender gap in crime and delinquency. Research consistently finds that females are much less likely than males to engage in illegal behavior. Scholarship examining gender and crime tends to follow one of three approaches: (1) Research at the macro-level examines national trends in women's offending compared to men's, assessing explanations of the change over time in the gender–crime gap. (2) Qualitative research illuminates how social environments shape women's decisions to commit crime. (3) Individual-level analyses of survey data center on sociopsychological explanations of why males are more likely than females to break the law. This article summarizes these approaches to studying gender and crime. It also discusses avenues for bridging macro- and individual-level explanations. The conclusions suggest areas in need of further research.

The 'gender gap' – or the significantly greater involvement of males than females in crime and delinquency – is one of the most robust findings in criminology. This gap has been identified across all types of data sources, including official data on arrests and criminal convictions, self-report data on delinquency and crime, and victimization data in which victims report the sex of perpetrators. Moreover, the gender gap appears to transcend time and space, as it has been documented cross nationally and over time (e.g., Smith and Visher, 1980; Lauritsen et al., 2009).

Although the persistence of a crime–gender gap has long been widely acknowledged, gender differences in crime received little attention in the empirical literature until the 1980s. Following the social movements of the 1960s, feminist criminologists in the 1970s critiqued the absence of research on female offending (e.g., Adler, 1975; Simon, 1975; Smart, 1976). Since that time, there has been a movement toward more serious considerations of female offending and the gender gap in crime and delinquency.

This article summarizes the research on crime and gender that has been conducted following the feminist critiques of the 1970s. It is organized around three typical approaches to the study of gender and crime and discusses key findings and arguments of each. Given space limitations, the article focuses on research on the causes of gender differences in offending and does not address gender and victimization or gender and criminal justice processing. For a review of those topics, see Kruttschnitt (1996).

Approaches to Studying Gender, Crime, and Delinquency

As with much social scientific research, empirical studies of gender and offending can be categorized according to levels of analysis, which guide the specific research questions addressed. One line of research focuses on the macro-level of analysis, examining rates of crime over time and across geographical areas. Research at this level seeks to explain the crime–gender gap as it is rooted in broad social patterns. Much of this macro-level research focuses on changes in the gender gap in crime rates over time and asks whether there has been convergence between female and male crime rates. This line of research suggests that there has been some convergence since the 1950s and 1960s in various nations, including England and Wales, Canada, and the United States (Box and Hale, 1983; Fox and Hartnagel, 1979; Steffensmeier, 1993). In some years during this time period, female crime rates increased faster than male rates, and at other times, male crime rates experienced sharper declines than female rates (Heimer, 2000). Moreover, the convergence in female and male rates is more pronounced during some periods for certain property crimes, such as larceny and fraud (Steffensmeier, 1993). Macro-level studies most often examine annual arrest or conviction rates, which are aggregated to the national level. The explanations offered tend to focus on women's liberation and worsening economic circumstances due to increases in female headship and other factors.

A second line of research utilizes individual-level data and sociopsychological explanations to account for gender differences in offending. Studies of this type often use quantitative data from self-report surveys of large national or local samples; most focus on juvenile delinquency. These surveys demonstrate that males are more likely than females to commit both serious

and minor violations of the law, but that the gender gap is most pronounced for the most serious and violent offenses. This line of work focuses on how sociopsychological factors – including family dynamics, beliefs, and attitudes – may contribute to the gender gap in crime and delinquency.

Beyond the distinction based on levels of analysis, research on gender and crime can be categorized by the type of methodology used. While the two lines of research discussed previously rely almost exclusively on quantitative data, a third line of research develops rich explanations for female offending based on qualitative analyses, reporting findings from open-ended interviews and ethnographic observations. Rather than examining female offending vis-à-vis male offending, this line of research most often focuses on female offenders, thus addressing differences in crime between groups of women, rather than comparing across gender.

The remainder of this article briefly reviews the three lines of research identified herein. It then examines attempts to bridge the macro- and individual-levels of analysis. It concludes by suggesting that future research continue to attempt to bridge levels of analysis, and to synthesize quantitative and qualitative research findings. In particular, the article argues that qualitative studies offer great potential to uncover the context and content of race, class, and gender inequalities that affect decisions to engage in crime and delinquency.

Research on the Narrowing of the Gender Gap over Time

Research on the narrowing of the gender gap in crime rates over time offers four explanations – women's liberation, economic marginalization, decline in chivalry, and domestic violence law enforcement. The liberation hypothesis proposes that women's crime rates increased during the 1960s and 1970s because women gained increased economic and social independence from men. One variant proposes that a convergence in gender roles led to a convergence in the gender gap in all types of crime (Adler, 1975; Hunnicutt and Broidy, 2004). Another variant proposes that women's increased labor force participation created new opportunities for crime in the workplace (Simon, 1975). Both variants have been criticized for assuming that labor force participation and improved economic conditions increase crime by females, whereas these conditions reduce crime by males (Chesney-Lind, 1997). Moreover, the narrowing of the gender gap is most pronounced for crimes that are consistent with women's preliberation roles – including larceny (theft), fraud, and forgery (see Steffensmeier, 1993). In addition, empirical research provides little evidence that women's labor force participation increases their crime (e.g., Box and Hale, 1983; for review, see Steffensmeier and Allan, 1996).

Consequently, contemporary studies often focus on the economic marginalization hypothesis, which proposes that the increased financial hardship of women relative to men has contributed to the narrowing gender gap in crime (Box, 1987; Steffensmeier, 1993). In general, these studies reveal that female arrest rates are often higher in cities where there are higher levels of poverty, joblessness, female-headed households, and other indicators of socioeconomic disadvantage, just as is the case for male arrest rates (Steffensmeier and Haynie, 2000; Heimer et al., 2006). While these findings suggest similarity in the structural factors affecting men's and women's arrest rates, little research has examined the effects of sex-specific measures of economic marginalization on women's arrest rates vis-à-vis men's. Future research should address the interplay between the specific elements of women's poverty that affect their crime rates compared to men's, including increasing rates of single motherhood, persistent gender inequality in wages, and changes in social welfare policies (Heimer, 2000; Heimer et al., 2006).

A third explanation of the narrowing of the gender–crime gap is the decline of chivalry hypothesis, which proposes that the convergence of female and male arrest rates is due in part to changing attitudes among law enforcement personnel. Specifically, the gender gap in female-to-male arrest rates reflects the chivalry of law enforcement personnel toward women (e.g., hesitation to arrest women), and the narrowing of the gap reflects a decline in this attitude over the years (Steffensmeier et al., 2005, 2006). Empirical evidence suggests that the decline of chivalry likely has had some effect on changes in the gender gap in crime, although economic factors are at least as important (Box and Hale, 1983; Steffensmeier and Allan, 1996; Steffensmeier and Haynie, 2000). However, the veracity of this hypothesis remains the subject of scholarly debate, with some researchers arguing that females are treated more harshly than males for some types of offenses (Chesney-Lind, 1997; Steffensmeier and Schwartz, 2004).

Relatedly, some scholars have argued that mandatory arrest policies in domestic violence cases may have led to more arrests of women over time as the arrest of both parties in these cases increased (Chesney-Lind, 2002; Steffensmeier et al., 2006). As a result of this shift, female arrest rates would presumably increase more than male rates. However, recent research by Lauritsen and colleagues (2009) compares Uniform Crime Report (UCR) violent crime arrest rate data over time with estimates of violent offending rates based on victim reports of offenders' gender using the National Crime Victimization Survey (NCVS) data over time. This study demonstrates that UCR arrest data and NCVS victim reports of offenders' sex produce very similar trends over time in the gender gap (Lauritsen et al., 2009). Given that victim report data are not subject to changes in police practice (Steffensmeier et al., 2006), the findings of Lauritsen and colleagues (2009) suggest that gender gap convergence in arrest rates is not entirely attributable to changes in police behavior.

Qualitative Research on Women's Offending

Qualitative studies of gender and crime typically do not focus simultaneously on male and female offenders. Instead, scholars interested in gender recently have begun to focus particularly on women offenders without directly confronting the gender gap in offending. This research offers in-depth analyses of the structural and situational factors associated with chronic offending among women. As a group, these studies suggest that poverty, unemployment, and single motherhood combine to create conditions of extreme economic hardship, which in turn are associated with events

and conditions of women's lives that increase the chances of a life of crime (Miller, 1986; Carlen, 1988; Daly, 1994; Richie, 1996; Maher, 1997; Baskin and Sommers, 1998; Miller, 2001). Consistent with the economic marginalization hypothesis, many qualitative studies find that female offenders are often socioeconomically disadvantaged. In general, qualitative studies report that female offenders are most often poor, unmarried, unemployed, and less educated (e.g., Wolfe et al., 1984). Of the women in this group who are employed, many work in low-paid service sector jobs without benefits. Given labor market inequalities along racial and class lines, women of color are also overrepresented (Campbell, 1984; Miller, 1986; Carlen, 1988; Daly, 1994; Maher, 1997; Baskin and Sommers, 1998). Similarly, other studies examine how living in a marginalized community facilitates entry into criminal networks and peer groups, which play an important role in initiating women into lives of crime and sustaining these lifestyles in the future (Miller, 1986; Baskin and Sommers, 1998; Miller, 2001). For example, several studies suggest that turning to crime is a rational attempt to support children and other family members when confronted with severe economic hardship (Miller, 1986; Carlen, 1988; Mullins and Wright, 2003).

In addition, many studies emphasize the connections between abuse during childhood, economic hardships, and criminal careers among women (Chesney-Lind and Rodriguez, 1983; Miller, 1986; Daly, 1994; Richie, 1996; Maher, 1997). Specifically, some researchers report that between one-third and nearly one-half of the women and girls participating in their studies experienced sexual and/or physical abuse before becoming adults (Daly, 1994; Miller, 2001). However, some scholars have proposed that focusing on women's victimization experiences as a primary factor driving their criminal offending is overly deterministic and obscures the choices women and girls make when becoming involved in crime and delinquency (Maher, 1997; Miller, 2001). Indeed, many studies find that women and men perpetrate crime and violence for similar underlying reasons (e.g., financial gain, perceived disrespect) (Miller, 2001, 2008; Mullins and Wright, 2003; Miller and Mullins, 2005; Kruttschnitt and Carbone-Lopez, 2006; Jones, 2010). These studies offer rich insight into the social world of female chronic offenders and, as we note in Section Bridging Levels of Explanation, open the door for the development of theories that can address macro-level as well as sociopsychological processes.

Self-Report Research on Gender and Juvenile Delinquency

Most research based on self-report surveys focuses on juvenile delinquency, especially common and less serious forms of delinquency. Much of the research in this tradition has focused on the application of and extension of existing criminological theory to explain sex differences in juvenile delinquency (for a review, see De Coster et al., 2012). The emphasis in this line of work typically is on understanding the sociopsychological mechanisms that contribute to the gender gap in delinquency. Recent research on these mechanisms suggests that the gender gap reflects both gender differences in exposure to factors that make law violation more likely as well as gender differences in the impact of these factors.

The sociopsychological mechanisms that have received the most attention in research on gender and delinquency occur within the family. Specifically, some research shows that part of the gender gap in delinquency is explained by the greater exposure of girls than boys both to direct parental controls, such as supervision and monitoring, and to indirect controls, such as emotional bonding (e.g., Jensen and Eve, 1979; Hagan et al., 1985, 1987; Chapple et al., 2010). Other research shows that the gender gap is not the simple outcome of girls being subject to higher levels of familial controls but also reflects the differential impact of these controls on girls versus boys. For instance, even though girls are more closely supervised, boys' delinquency appears to be influenced more strongly by supervision and monitoring; in contrast, girls' delinquency is influenced more strongly by emotional bonds to their families (Heimer and De Coster, 1999; Hagan, 1989; Chapple et al., 2005; alternatively see Kruttschnitt, 1996). In short, it may be that parents control girls' misbehavior through subtle, covert control mechanisms (e.g., emotional bonding), whereas controlling boys' misbehavior requires more direct, overt strategies (e.g., supervision).

Another individual-level factor that has received attention is gender roles. The argument, related to the liberation thesis discussed before, is that feminine roles restrain delinquency more than masculine roles do (e.g., Shover and Norland, 1979). Many studies of gender roles and delinquency appeared in the late 1970s. However, the empirical research was inconsistent, perhaps because gender roles were operationalized in diverse ways across studies, often including traits, attitudes, and familial controls as well as behavioral expectations or roles.

The more recent trend has been to focus on cultural definitions of gender or hegemonic gender definitions, which are widely accepted beliefs and attitudes that support the subordination of females to males under patriarchy. Hegemonic gender definitions depict a feminine ideal that includes a high capacity for nurturance, passivity, connectedness to others, and physical weakness; in contrast, the masculine ideal emphasizes competitiveness, aggressiveness, independence, and strength. Definitions of femininity thus are more inconsistent than definitions of masculinity with victimizing others physically or taking their property. Some empirical research shows that acceptance of these gender definitions is an important contributor to the gender gap in law violation (Simpson and Elis, 1995; Heimer and De Coster, 1999; McCarthy et al., 1999). Other research suggests that boys who have internalized hegemonic definitions of masculinity are more likely to engage in crime and violence (Messerschmidt, 1993, 2000; Simpson and Elis, 1995; Heimer, 1996; Miller, 2001; Mullins et al., 2004; alternatively, see Morash and Chesney-Lind, 1991).

A third individual-level factor that has received attention in the literature on gender and delinquency is attitudes toward risk taking. The hypothesis here is that youths who develop a taste for risk will be more likely than others to engage in thrill-seeking behavior, including delinquency. The power-control theory of gender and delinquency, discussed

following, proposes that one reason males are more likely than females to be delinquent is that males are socialized to prefer risk taking (Hagan 1989; McCarthy et al., 1999; Blackwell et al., 2002; Hagan et al., 2004).

Bridging Levels of Explanation

To date, most research on gender and criminal offending has focused on either the macro-level or sociopsychological explanations discussed previously and rarely has pursued links between the two. One notable exception is Hagan's power-control theory, which argues that parents' positions in the workplace shape their parenting practices, including their supervision of children, emotional bonding with children, and the gendered socialization of children (Hagan et al., 1985, 1987). More specifically, when fathers have more power than mothers in their work or professional lives, mothers experience paternalistic control within the family. Mothers reproduce this arrangement with their children by subjecting daughters to higher levels of control than sons, encouraging risk preferences more among sons than daughters, and inculcating sons and daughters with traditional gendered schemas or ideologies (Hagan et al., 1987; McCarthy et al., 1999; Hagan et al., 2004). When parents have more equal power in their work lives, they engage in a more egalitarian partnership that they pass on to their sons and daughters. That is, sons and daughters in these more egalitarian families are treated rather similarly, resulting in a narrowing of the gender gap in law violation. Some research supports these arguments (Blackwell and Reed, 2003); however, others fail to replicate key findings from the theory (Singer and Levine, 1988; Jensen and Thompson, 1990; Blackwell, 2000).

Another emerging perspective on gender and crime with the potential to bridge levels of analysis is the work of Messerschmidt (e.g., 1993, 2000). He argues that males may attempt to display masculinity through crime and violence when legitimate channels for claiming gender are blocked by structural barriers, such as unemployment and poverty (Messerschmidt, 1993). Messerschmidt (2000) further explores links between structural barriers and sociopsychological mechanisms in his analysis of boys' violence. He argues that much of this violence is a result of the interplay between patriarchal structures, social class, and sociopsychological processes, such as alienation at school, victimization, body image, and hegemonic masculine ideals. While this work moves toward bridging levels in analyzing masculinity and crime, it does not address femininity and crime. Jody Miller (2002) argues, for instance, that gender is overemphasized in Messerschmidt's structured action theory, suggesting that violence among women and girls cannot be explained effectively with an emphasis on gendered displays. For example, several studies find that girls who engage in violent behavior are not necessarily attempting to claim gender, but rather to maintain their hard-earned respected positions as females in male-dominated groups (Messerschmidt, 1997, 2012; Miller, 2001; Jones, 2010).

Some of the qualitative research discussed in Section Qualitative Research on Women's Offending also could serve as a springboard for the development of theories that bridge the macro- and sociopsychological levels of analysis. Many of these studies examine how economic hardship and cultural contexts influence individuals' perceptions and decisions about crime (e.g., Miller, 1986; Maher, 1997; Baskin and Sommers, 1998; Miller, 2001; Kruttschnitt and Carbone-Lopez, 2006). As De Coster and Heimer (2006: 147) observe, intersecting inequalities influence behavior in ways that scholars are only beginning to understand. Future research must consider definitions of situations as well as role-taking processes to understand the ways that social structures, such as race, class, and gender inequality influence individual actions. The next step would be to account for these findings by specifying a theory of the links between the macro- and individual-level mechanisms leading to women's crime, and then broaden this explanation to address gender differences in crime.

Directions for Future Research

Up to the end of the twentieth century, the strands of research discussed herein have remained relatively isolated from one another. In addition, research was focused more on uncovering empirical relationships than on building comprehensive theories of gender, crime, and delinquency. Future research will need to develop rigorous theoretical arguments that link levels of analysis, drawing links between the mechanisms identified by macro-level research on changes in the gender gap and individual-level survey research. Moreover, research must bridge the divide between quantitative and qualitative research, combining findings from both to generate more complete explanations of gender, crime, and delinquency. In particular, quantitative methods may be more useful for uncovering the factors underlying structural-level patterns of crime as they emerge from the intersections of race, class, and gender inequalities, and qualitative research is critical for adding depth and greater understanding of how these factors combine to explain offending in the daily life experiences of women.

Crime, Desistance, and Persistence

Abstract

This article on persistence and desistance in criminal offending examines key areas related to the question of why some criminal offenders stop their offending (desist) while other criminal offenders continue to offend for longer periods of time (persist). Included in the article are discussions of this research literature's foundations in the age–crime curve, common theoretical explanations, and key methodological issues including both definitional and modeling challenges. The discussion concludes by describing key empirical findings related to the association of adult life events with changes in offending patterns and finally identifies areas for future inquiry.

Introduction

Broadly understood, the issues of persistence and desistance boil down to a simple question about criminal offenders: why do some continue to offend (persist) while others stop offending (desist)? Answers to this seemingly simple question have exposed a number of issues that have now generated over two decades of debate among criminologists. The debates have included theoretical explanations, how to define the two terms, the appropriate methodology to study them, and the relevance of adult life events.

The Rise of Interest

Interest in persistence and desistance grew rapidly beginning in the mid-1980s, largely motivated by a desire to understand one of the oldest 'facts' of criminology – the age–crime curve (Piquero et al., 2003). The age–crime curve depicts the following empirical relationship between age and crime: in the aggregate, criminal offending rates rapidly increase during early adolescence, peak during late adolescence or early adulthood (violent crimes typically peak later than property crimes), and then subsequently decline over the remaining age distribution, with the decline generally steeper during the 20s and 30s. Figure 1 graphically illustrates the age–crime curve using the aggregate age-specific arrest rates for burglary in the United States in 2010.

Indeed, it is the shape of the age–crime curve that has yielded interest in the nature of criminal offending across age. Although historically criminologists have focused on adolescent offenders and the differences between those with higher and lower rates of offending, over the last 25 years, more interest has shifted to understanding the 'right tail' of this distribution. Looking beyond the key finding that offending is nearly ubiquitous during adolescence, the declining arrest rate in the right tail indicates that individuals either stop or reduce their offending as they age. Questions are thus posed about why some offenders change (i.e., desist) while others continue offending into adulthood (i.e., persist). Explaining these patterns largely focuses on the role of adult life events (such as marriage and employment) for understanding the processes of both persistence (continuity) and desistance (change).

The relationship between age and crime has also generated considerable debate and controversy, especially in the late 1980s and early 1990s (see Piquero et al., 2003). Much of the controversy surrounding the age–crime curve focuses on a key question: does the aggregate pattern seen in Figure 1 uniformly apply at the individual level? This question posits the possibility that the relationship between age and crime could vary either between individual offenders or between different groups of offenders. This possibility is important because if the relationship depicted at the aggregate level does indeed apply to everyone at the individual level, then the relationship between age and crime would be 'inexplicable' because it does not vary, which would render desistance and persistence as

Figure 1 Age-specific arrest rates for burglary, 2010. Source: Snyder, H.N., 2012. Arrest in the United States, 1990–2010. http://www.bjs.gov/index.cfm?ty¼pbdetail&iid¼4515 (accessed 28.10.13.).

uniform processes; however, if it varies at the individual level and/or varies between different groups of offenders, then there would be differences that require both empirical investigation and theoretical explanation.

Three Key Theories

Research investigating issues related to persistence or desistance have often been examined through three broad perspectives: population heterogeneity, state dependence, and developmental taxonomic. These three perspectives are often represented using three specific theoretical explanations, respectively: Gottfredson and Hirschi's (1990) self-control theory, Sampson and Laub's (1993; Laub and Sampson, 2003) informal social control theory, and Moffitt's (1993) dual taxonomy theory. Each of these theories differs in their explanations of the age–crime relationship, the possibility of and/or the explanations for change, and whether life events matter for explaining persistence or desistance.

Gottfredson and Hirschi's self-control theory (1990) articulates the three defining aspects of population heterogeneity theories (Thornberry et al., 2012). First, the causes of crime develop early in the life course; second, these causes are stable (in a relative sense) across age and differences between people persist across time; and third, observed changes with age reflect the direct effect of aging/maturational processes that occur uniformly for all offenders. They argue that a person's level of self-control develops by approximately age 8 years as a consequence of the degree to which they are exposed to effective parenting. After childhood, however, there is relative stability between people in their levels of self-control. Therefore, a person's criminal propensity, once formed, is viewed as relatively immutable to meaningful change. More importantly, all dimensions of criminal offending, including onset, frequency, persistence, and desistance, are argued to be explained by a person's self-control.

Individuals with low self-control are argued to have a higher criminal propensity and to take advantage of opportunities to engage in criminal behavior earlier in the life course, at a higher rate, and for longer periods of time compared to individuals with higher self-control levels. Thus, persisters are individuals with lower levels of self-control, while desisters have higher levels of self-control. Gottfredson and Hirschi argue that all offenders reduce their offending as they age, thereby representing a uniform, natural aging process affecting all offenders at similar ages and rates. Therefore, the relationship between age and crime is said to be 'invariant' between people and 'inexplicable' by sociological and psychological processes.

Further, the authors of this theory argue that people self-select into both life experiences (e.g., whether they are employed in a stable job or in a stable marriage) and social environments on the basis of their level of self-control, and thus the association of life events with crime is spuriously due to self-control differences. Stated differently, the processes of both persistence and desistance are the outcomes of a person's level of self-control.

Sampson and Laub's theory, on the other hand, takes an opposite position and maintains that adult life events, or the lack thereof, are what matter most for explaining both desistance (change) and persistence (continuity). They draw on the core underlying assumptions of both the life course perspective and state dependence theories to argue that a person's level of criminal propensity can change as a consequence of changing social environments and lived social experiences. Furthermore, because the presence, absence, and timing of these changing social environments and life experiences will vary substantially across people, there will be expected variability between people in the relationship between age and crime (Thornberry et al., 2012). Thus, rather than envisioning uniformity in the desistance process, this theoretical framework expects variability between people in their patterns of desistance in terms of both the age at which it begins and the rate at which it progresses.

Sampson and Laub's theory is an informal social control theory that proposes a person's willingness to engage in crime is a function of the current strength of their bonds to the age-graded institutions of informal social control. They primarily focus on explaining patterns of persistence and desistance in adulthood by focusing on two key adult social institutions: marriage and employment. Experiencing these key adult life events, whether by chance or choice, results in changing levels of informal social control in offenders' lives. Importantly, they argue that the quality of the relationships and attachments to these social institutions matters more than their mere occurrence. Desistance is facilitated to the degree that getting married or finding a stable job results in the offender becoming invested in those relationships. Crucial to this perspective is recognizing that changes in offending patterns are characterized as a dynamically evolving process rather than an isolated discrete event.

Persistence in crime, on the other hand, results from the lack of informal social control due to the negative consequences of prior criminal behavior, including prison terms and concomitant labeling effects, that serve to further attenuate a person's exposure to key institutions of informal social control. Engaging in crime is thus seen as exerting a causal effect on the likelihood of future crime as it both weakens the offender's existing social bond and reduces opportunities to experience other life events. In summary, Sampson and Laub envision that within-individual changes in the strength of social bonds across age are the primary mechanisms for both persistence and desistance, and that change is ever present.

Despite the obvious contrasts, both of the prior theories use the same general theoretical framework to explain both persistence and desistance processes. Moffitt's dual taxonomy theory, on the other hand, explains each process separately, with each explanation attached to a single 'type' of offender.

The offender type labeled 'life-course-persistent' is argued to be responsible for the pattern of persistence in offending, as the name aptly implies. Argued to represent less than 10% of the population, this group's persistence in criminal and antisocial behavior is explained as the result of the negative, reciprocal interaction between a child with neuropsychological deficits and parents with ineffective parenting skills and limited resources; this reciprocal interaction ultimately causes the socialization process to fail and yields a person with a stable antisocial behavioral repertoire impervious to change and likely expressed in all life domains. This group is expected to fail in a variety of familial, educational, and interpersonal

outcomes, and indeed has been argued to likely select life experiences that are either consistent with or serve to reinforce their antisocial tendencies rather than provide any opportunity for change; thus, persistence in crime during adulthood defines this group.

Patterns of desistance are explained by the more common offender type, 'adolescence-limited' offenders. Compared to life-course persistent offenders, this group (about 90% of the population) both begins and ends their offending during adolescence and commits less serious offenses. Their rapidly changing likelihood of offending is due to the strain-inducing 'maturity gap' between biological and social maturity found in modern adolescence. Although they have become biologically mature like adults (and capable of reproducing), they remain socially restricted from acting like autonomous adults who get to decide when, where, and what activities they do. This strain is reduced, however, as they legitimately gain access to the adult maturity they have so desired. Thus, with increased independence, the benefits of delinquent/criminal behavior become less rewarding and also threaten their newfound autonomy, and they desist as a result. Thus, desistance defines this group, and given the size of this group, it is their rapidly changing offending patterns that are argued to largely generate the shape of the age–crime curve.

Methodological Issues

The Definition Problem

Among criminologists, there is at least one area of agreement as it relates to both desistance and persistence – scholars agree that there is a lack of consensus on how to define the terms conceptually and operationally (Brame et al., 2003; Bushway et al., 2001, 2003, 2004; Kazemian, 2007; Laub and Sampson, 2001, 2003; Piquero, 2004, 2009; Piquero et al., 2003, 2012). The most central issue in this definition problem concerns the distinction between 'static' and 'dynamic/process' definitions of desistance.

The static definition, which has been the most frequently applied definition in the research, "… counts everyone who offends at least once before a specified cutoff in a follow-up period but not afterward as a desister. Individuals who offend in both periods are termed persisters" (Bushway et al., 2003: 130). In the static definition, desisters are akin to smokers who go 'cold turkey,' and they move abruptly from 'offender' to 'nonoffender,' thereby emphasizing the qualitative state of having 'terminated' their offending. The focus of studies using this definition is a 'between-groups' analysis to examine the measured characteristics associated with membership in the two mutually exclusive groups (desisters and persisters). One significant limitation of this definition is that the short-term follow-up periods in most studies do not allow researchers to distinguish between 'true desistance' (or the true, complete 'termination' of offending) and 'false desistance' (a nonpermanent lull in offending that is eventually followed by subsequent criminal offending) (Bushway et al., 2003).

Broadly stated, the dynamic or process definition views desistance as a discernible reduction in criminal offending. Thus, rather than emphasizing the complete absence of subsequent offending during a particular time period, as with the static definition, the dynamic/process definition emphasizes the "quantitative change in frequency [of offending] from higher to lower levels" (Bushway et al., 2001: 495). Here, desisters are akin to smokers who eventually become nonsmokers by gradually reducing the number of cigarettes smoked over time. Desistance, therefore, is a process unfolding gradually over time and indeed may unfold faster or slower, earlier or later, for different offenders. The focus here is largely on the nature of the changing offending patterns 'within person' over time, and studies using this definition are more interested in examining the observed events and changing characteristics within a person over time that are associated with either initiating and/or enhancing the reduction in offending.

Although the field has expressed a preference for the dynamic definition, disagreement still remains over the precise definition of 'desistance as a process' (Mulvey et al., 2004). At issue is whether desistance as a process means (1) a reduction or a deceleration in frequency or severity of offending (Fagan, 1989), (2) offending must be reduced to a level near zero but not necessarily zero (Brame et al., 2003), (3) a reduction in a latent criminal propensity to a level not significantly different from zero (Bushway et al., 2001), (4) a discrete period of time where offenders maintain the state of being crime-free (Maruna, 2001), or (5) a specific theoretical causal process that underlies the termination of offending (Laub and Sampson, 2001, 2003).

Similar challenges emerge when defining 'persistence' in offending, as it is 'seemingly the conceptual reverse' of desistance (Laub and Sampson, 2003: 17; Piquero, 2009). Laub and Sampson (2003: 150) associate the following words with persistent offending: 'enduring, repetitious, and tenacious.' But exactly how 'enduring,' how 'repetitious,' and how 'tenacious' are not agreed upon, and thus there is no commonly or broadly accepted definition of persistence (Laub and Sampson, 2001; Piquero, 2009). Piquero (2009: 272) asks, "Is persistence made up of offense frequency, chronicity, or a time-span or length of criminal involvement, or some combination thereof?" He continues by positing at least two key conditions necessary to generate a valid definition of persistence. First, persistent offenders, must meet some minimum threshold of offending, and second they must be involved in crime for some minimum number of phases of the life course. However, the specific minimums for those have not been specified or agreed upon.

The concept of 'intermittent offending' adds further ambiguity to these definitional conundrums. Intermittent offenders are those who drift in and out of criminal and noncriminal behaviors in an often termed 'zigzag' style or pattern of offending (Laub and Sampson, 2003). Intermittent offending thus specifically acknowledges the 'lulls' in offending over time. The goal of investigating such intermittent offending patterns is to uncover the factors associated with the back and forth movement between offending and nonoffending. But much like persistence and desistance, there is no accepted definition of intermittent offending (Piquero, 2004). Further, the manner in which it has often been empirically operationalized, such as "people who are exhibiting longer waiting times between offenses" (Baker et al., 2013: 19), can clearly blur the

boundaries between intermittence and both persistence and desistance. Indeed, as Mulvey et al. (2004) discuss, one appealing aspect of defining desistance as a decrease in offending over time is that it specifically allows for the inclusion of intermittent offending.

One of the main reasons why this definition problem is so critical is the possibility for 'overlap' in the definitions. Indeed, using the definitions of desistance as a declining rate of offending, persistence as criminal behavior that occurs over multiple phases of the life course, and intermittence as increased waiting times between offenses, it is entirely possible that one individual offender, using the exact same measured data, could be simultaneously defined as an offender in the process of desistance, as a persistent offender, and as an intermittent offender. One researcher's persister can be another researcher's desister and yet another researcher's intermittent offender. Importantly, however, this overlap of definitions emphasizes a critical point raised by both Laub and Sampson (2003: 287) and Maruna (2001: 75): while the dichotomy of 'persister/desister' is often used to imply that these labels apply to distinct kinds of people, these terms should only be used at most as 'heuristic devices' because they may in fact be the same 'individuals in different stages of the process of change.'

Operationalization Complications

Besides the problem of conceptually defining desistance and persistence, there are also a number of important issues related to the operationalization and empirical measurement of them. First is the issue of data, whether to measure criminal behavior using official (arrest) data or self-report data. Compared to official data, self-report data may find more persistence or 'delayed desistance' because some crimes are less likely reported to the authorities and therefore less likely to be captured in official data, but still likely to be captured in self-report data (Farrington, 2007). Official data, on the other hand, carries the bias of decision makers in the criminal justice system. Ideally, studies would use both measures of criminal behavior, but that is rare.

Other questions emerge about the nature of the criminal offenses committed over time and how they should be included in measuring desistance. In addition to offending frequency and seriousness, is versatility/specialization in offending relevant? Should measures of desistance allow for 'offense displacement' (Massoglia, 2006), which describes how offenders may vary or shift the types of offenses they commit across age? If offenders shift from violent crimes to drug crimes, is this evidence of desistance? And perhaps most importantly, can one simultaneously combine many of these issues (frequency, seriousness, versatility, displacement) into a more holistic view of desistance?

A third measurement issue concerns exactly who should be included in studies of desistance. Laub and Sampson (2001) argue for a minimum threshold of prior offending to be met in order to be included in a study of desistance and specifically argue that occasional, low-rate offenders should be excluded from studies of desistance. Not all criminologists agree. Finally, given that individuals highly involved in crime are more likely to experience both death and incarceration, it has been argued that adjustments for these outcomes should be made in order to not explain a lack of new offenses as desistance when in fact the offender was either incarcerated or deceased.

These many issues concerning definitions and measurement may seem overly complicating; however, definitions and operationalizations matter. For example, both Bushway et al. (2003) and Brame et al. (2003) find that different definitions applied to the same data can yield different conclusions about how many offenders 'desist' and exactly who is identified as a 'desister.' Different concepts, different data, and different empirical measures all express particular ideas and ultimately may mean different answers. Examining the definitions, samples, and measures used in any study is critical to contextualizing the results because both findings and generalizability can be affected by them (Piquero et al., 2012). Further research is needed to explore conceptual and operational consequences on individual samples. Yet, until a greater understanding and consensus emerges, readers of the literature would be well served to scrutinize the definitions, samples, and measures in any given study and to not overgeneralize results.

Methods of Analysis

Since most studies of desistance and persistence employ the static definition, they generally analyze the data using standard methods of analysis (such as logistic regression) that allow for a between-group analysis of the characteristics significantly associated with distinguishing desisters from persisters. In contrast, there is more uncertainty about the appropriate method of analysis when one adopts the process definition. Studies using the process definition typically choose between one of two statistical approaches to modeling changing offending patterns over time: the group-based trajectory model (GBTM) and the growth curve model (GCM). Both methods examine heterogeneity in offending trajectories over time while also allowing for examining the effects of time-varying covariates on offending patterns, but they do so using different assumptions. Of particular note is the manner in which each accounts for heterogeneity in the distribution of offending trajectories. This brief description of these two approaches draws on several excellent, relatively nontechnical overviews found in Brame et al. (2012), Nagin (2010), Osgood (2010), and Sullivan and Piquero (2011).

The GBTM accounts for the heterogeneity by 'grouping' individuals together into a finite number of groups, with each group possessing a distinct offending trajectory in terms of its level of offending and/or its developmental pattern over time. This allows each of the estimated groups to have a distinct trajectory shape over time.

The number of groups in any data set is empirically determined based on a number of considerations, including the fit of the model. After the necessary number of groups has been decided and the model estimated, each individual is assigned to the group that most closely resembles their observed offending pattern. The model estimates also allow for a graphical depiction of each group's trajectory, as well as the expected percentage of the population belonging to each group. Analyses can also examine whether specific predictors are associated with membership in the different groups.

Further, since individuals with similar offending patterns over time are assigned to the same group, a variety of methods are then available to control for possible selection effects. For example, analyses have been completed using just the members of particular groups because all members within each group have a similar criminal propensity. Similarly, propensity score methods (which match people on the basis of observed variables) have also been used to match members within a trajectory group (Nagin, 2010). Finally, time-varying variables can also be included in the estimation of the GBTM itself to examine whether the time-varying variable impacts the offending rate itself, and separate effects can also be estimated for each group, which also allows one to control for criminal propensity differences.

The main controversy of this method, however, concerns the estimated 'groups.' The notable concern has been over the possible reification of the groups as real, a priori distinct groups, which has significant implications for both theory and policy. If the estimated groups arise out of the 'approximation' process of the GBTM whereby the continuous distribution of trajectories is approximated through the use of discrete groups (see Nagin, 2010), then the groups are not real, distinct groups, but they may still be treated as such. This concern has been raised in light of the 'chronic offender' groups that are often found, especially since the chronic offender group has long been a seductive target for selective incapacitation policies.

The GCM approach, on the other hand, accounts for the heterogeneity in offending by imposing mathematical assumptions about distributions of the individual offending trajectories, or more specifically, the distribution of the intercept and growth (slope) parameters. As part of this assumption of the distribution of the trajectories, the method assumes there is a common, average trajectory descriptive of the population as a whole, as well as usually specifying that the individual trajectories are distributed about the overall average trajectory according to the multivariate normal distribution. Thus, in comparison to the GBTM, the GCM approach assumes that all individual trajectories are distributed about a common, average trajectory. The power of these models principally lies in their ability to examine what individual characteristics can account for the variability of the trajectories about the average trajectory, both between persons (using individual characteristics that do not vary across time) and within individuals (using individual characteristics that vary across time). It is the within-individual part of these models that has been creatively exploited to examine the effect of life events on changing offending patterns as it allows for examining the effects of events while holding constant all of the time-stable characteristics of the person, both measured (such as gender) and unmeasured (such as a time stable criminal propensity) (Osgood, 2010); in effect, because each person is essentially acting as their own control in this part of the model, this allows one to account for the selection effect argument that argues time-stable traits explain the occurrence of both life events and criminal offending patterns. However, it cannot account for time-varying selection effect processes or unmeasured time-varying characteristics (Osgood, 2010; Siennick and Osgood, 2008).

It is perhaps best to think of these two approaches as mutually beneficial (Nagin, 2010). The GBTM's key strength lies in its ability to uncover distinct trajectory shapes that are allowed to vary in terms of their developmental shape and to examine how characteristics are associated with and predict group membership. The key strength of the GCM is its ability to examine how the time-varying characteristics of the individuals can be used to explain within-person changes in offending (Nagin, 2010). Since there will be continuing interest in both discovering and examining trajectories displaying patterns of persistence and/or desistance (the strength of GBTM), as well as examining the characteristics associated with within-individual changes in offending patterns (the strength of GCM), both methods will continue to add insight to our understanding of the complex processes of desistance and persistence in unique, yet complementary, ways.

Key Empirical Findings: Trajectories of Criminal Offending, Salient Life Events, and the Prediction Problem

Key conclusions and empirical findings of three research areas related to the empirical study of persistence and desistance are briefly and broadly discussed here. Key studies in each area are cited for further background information and details on these topics.

Criminal Offending Trajectories

Rooted in the age–crime curve debate and largely utilizing the group-based trajectory methods described above, there were already over 80 studies on the nature of criminal offending trajectories by 2008 (Piquero, 2008), and more have appeared since then. Key reviews can be found in Piquero (2008), Van Dulmen et al. (2009), and Jennings and Reingle (2012).

Several notable, generally consistent conclusions emerge from the studies examining criminal trajectories. First, there is a considerable amount of heterogeneity with respect to the nature of criminal trajectories across age; this relevant heterogeneity in the offending patterns can be specified in terms of when they begin, the rate at which they increase, the age at which they peak, the age at which they begin to decrease, the rate at which they decrease, and when/if they reach a point where the offending rate is approximately zero. This heterogeneity sometimes results in trajectories that, although very similar at one point in time, ultimately become quite dissimilar at a later point in time, including trajectories crossing over each other (e.g., see Bushway et al., 2003: Figure 1). Ultimately this broad conclusion sheds doubt on the arguments that the relationship between age and crime is invariant and that the aggregate age–crime curve applies at the individual level; further, it supports arguments of Sampson and Laub that differences in adult offending patterns cannot be explained purely on the basis of earlier preexisting differences in offending.

Second, the vast majority of offending trajectories rise to their peak rates and then decline with age, although the specific peak age and rate of this decline varies across trajectories. Regardless, by early to midadulthood, most estimated

trajectories are either in the 'process of desistance' or appear to have terminated their offending, but the process itself is clearly variable across the groups. Third, at least one or two of the estimated groups typically engage in crime rather persistently across age, and are often labeled with the modifiers 'persister,' 'chronic,' or 'high-rate' (see Table 1 of Jennings and Reingle, 2012 and Table 14.1 of Van Dulmen et al., 2009). Thus, although it has been argued that it is inherently problematic to find the 'life-course-persistent' offender type because of censoring issues such as short follow-ups, death, and incarceration and because the GBTM/GCM methods have been argued to be biased against finding such offenders (Bushway, 2013), it does appear to be that there is a small group of offenders who, at least more or less, engage in crime rather persistently across age. The second and third conclusions noted here, however, are not inconsistent with each other, especially when one contextualizes the problem of defining terms like desistance, persistence, and chronic. For example, a persistent offender group could be criminally active in a number of different decades in life, but they could also be much more involved in crime during their earlier periods of life.

Marriage, Employment, and Other Adult Life Events

Positive life events experienced during adulthood are the primary focus for explaining the heterogeneity in offending trajectories across age because the declines in crime occur at times when adult life event transitions are common. Broad, summary conclusions from this research, especially those regarding marriage and employment, are included here. Excellent detailed reviews on these topics and their methodological challenges can be found in Laub and Sampson (2001), Siennick and Osgood (2008), Uggen and Wakefield (2008), and Horney et al. (2012). To be clear, determining the 'effect' of life events is methodologically challenging because one must effectively account for the 'selection' arguments that the same individuals who experience various life events could be the same people likely to desist for other reasons (e.g., because they have higher self-control).

Marriage is both the most studied life event and the one demonstrating the largest and most consistent association with reductions in criminal offending. This 'good marriage' effect has proven robust across studies that differ in research design (cross-sectional and longitudinal designs), time period, geographic area, operationalization of crime (self-report and official data), and sample type (general population and offender-based samples) (Horney et al., 2012; Siennick and Osgood, 2008). This robust marriage effect is further strengthened by the many studies employing the best and most powerful methods of accounting for possible selection effects, including propensity score methods, estimating the effect within distinct trajectory groups, and through analyses of within-individual change that control for all time-stable differences between people.

However, the marriage effect may in fact be qualified by gender because it appears to be more beneficial for men, but further research is needed. Future additional research also needs to expand to include romantic partners and cohabitation more generally, as well as whether the effect of marriage depends on the level of prior criminal activity (whether it is stronger for less/more serious offenders), the possible reciprocal relationship between crime and marriage, and how the level of criminality/deviance of the marital/romantic partner may alter the effect size or direction. And despite considerable efforts into determining the specific causal mechanisms underlying why marriage matters, researchers admit a variety of sources could potentially explain it (Laub and Sampson, 2003): the investment and strength of the marriage, changing patterns of associations with (deviant) peers, changing routine activities, changing places of residence and neighborhoods, increased levels of supervision and monitoring, and/or as a result of cognitive identity transformations. Future research is needed to help determine the specific intervening, mediating mechanism(s) through which the marriage effect is transmitted.

Although studied less than marriage, employment is another life event subjected to empirical examination for its association with desistance/persistence, but its effects are both less consistent and weaker than those associated with marriage; further, estimated effects are often found to 'depend on something else' (Siennick and Osgood, 2008: 180). For example, employment appears to have differing effects across age. After employing effective statistical controls for possible selection effects, there appears to be no association of employment with either increased or decreased levels of criminal activity for adolescents. For older adults (especially those beyond age 26 years), however, employment appears to significantly help facilitate desistance. Conclusions on the importance of job stability and job quality remain unclear, including how job quality could influence the overall relationship between employment and crime. Additionally, the relationship between employment and crime may vary by offense type, with employment possibly increasing property offending and decreasing violent offending. Because studies of employment tend to not be as methodologically rigorous as those examining the effect of marriage, conclusions regarding the effects of employment also tend to be more tentative, lending greater uncertainty to the general conclusions and leaving wide open the areas for much future research.

Beyond marriage and employment, however, many other theoretically interesting adult life events have yet to be studied as frequently or extensively. For example, whether/how parenthood, military service, religion and spirituality, and penal sanctioning and imprisonment are associated with patterns of desistance/persistence are all issues awaiting additional research. For example, initial findings examining the link of both military service and parenthood to changes in offending have produced variable, mixed findings. Also, it has been noted that because some individuals begin their pattern of desistance during adolescence, prior in time to the occurrence of any key adult life events, future research needs to delineate and study the role of important adolescent life events and processes as well (Laub and Boonstoppel, 2012). Therefore, as the field continues to examine these issues, the many and nuanced ways in which many life events may or may not be associated with persistence and desistance will certainly become clearer.

The Prospective Prediction Problem

The discovery of the 'chronic offender' was critical for generating interest in whether it was possible to identify these persistent 'career criminals' early in their life courses in order to incapacitate them. Subsequent research indicated that the early prediction of chronic offenders was fraught with prediction errors, especially false-positive errors (falsely predicting someone to be a chronic offender).

The issue of whether it is possible to prospectively predict long-term crime outcomes is still present today. The ascent of developmental theories that predict distinct groups of offenders along with the rise of the GBTM methodology, which generates 'groups' (whether real or approximations), has generated interest in whether membership in the groups could be prospectively predicted on the basis of early risk factors. Although groups with distinctive offending trajectories can clearly be retrospectively identified, including groups labeled as 'persisters' and 'desisters,' subsequent attempts to accurately predict group membership on the basis of early (childhood) risk factors have resulted in the conclusion that such prospective prediction is not possible with the currently and commonly available predictors (Bersani et al., 2009; Sampson and Laub, 2003). Although certain variables have been found to have significant associations with membership in certain groups, the predictive results from those associations are ineffective at accurately discriminating group membership. Thus, although we know there are people who desist earlier in the life course and people who will persist over longer periods of the life course, studies have not been able to effectively predict which offenders will be the persisters or desisters. Consider three important, interrelated points with respect to this finding. First, it is consistent with the previous discussion that there is heterogeneity in long-term offending patterns and that the relationship between age and crime is variable. Second, it indicates that even for high-rate offenders, change over the life course is possible. Finally, it highlights the importance of life experiences in late adolescence and adulthood; unless one knows prospectively what life events a person will experience, how those events are specifically related to crime, and how that person will respond to those events, it will be impossible to predict their specific offending rate in the future (see Laub et al., 2006). Further, it reinforces the previous conclusion of the need for further research to empirically uncover the specific life events, beyond marriage, that are significantly associated with changes in offending.

Key Emerging Issues

Despite the historically heavily quantitative nature of studies on desistance and persistence, a budding interest in the subjective accounts of the desistance and persistence processes has increased interest in qualitative methods, especially life history narratives. Qualitative methods allow for important in-depth analysis from the offenders' subjective perspective, allowing offenders to interpret their present in light of both their past and their anticipated future to explain how they 'make sense of their lives' (Maruna, 2001: 7). These narratives allow for examination of possible changes in cognitive processes and identity and specific causal mechanisms though which salient life events are linked to crime, including the interplay between human agency (purposeful choice) and constrained structural contexts (Laub and Sampson, 2003).

Indeed, the issues of the future self, cognitive processes, identity change, and human agency all strike at the core of the disputes between differing perspectives on the relevant subjective factors and processes that may play crucial roles in the desistance/persistence process. For example, Maruna (2001) argues that offenders who desist have been able to cognitively reconstruct themselves as 'making good' through a 'redemption script,' but they do not literally cast off their old identity. Paternoster and Bushway (2009), on the other hand, argue that a necessary, gradual, and complete identity change from offender to nonoffender results from the 'fear of the future self,' as well as that beginning the process of such identity change is required prior in time to both accessing and benefitting from adult life events. Laub and Sampson (2003), in contrast, argue that it is not necessary for offenders to undergo an identity change to benefit from life events or desist, and that, in fact, life events themselves can generate 'desistance by default.' So, although there is growing interest in the importance of subjective processes, answers as to which perspectives have more empirical validity await future qualitative (and quantitative) research.

Moving forward, three empirical issues will likely set the stage upon which many of the interesting questions discussed above concerning persistence and desistance will play out. First, studies on these topics nearly always note that the generalizability of findings remains a critical empirical limitation because most analyses are based on predominantly white, male samples from the United States or other Western industrialized nations and are specific to time and place. The degree to which any reported findings generalize across other important demographic subgroups, including Hispanics, African-Americans, and females, as well as other places and times, may either unlock new findings or fortify current findings about how and why criminal offenders persist or desist. For example, what are the consequences of recent changes in patterns of marriage, childbirth, education, and employment for the desistance processes of young adults (Horney et al., 2012)?

Second, there is a need to understand the nuanced ways in which life events and criminal behavior are related. For example, data and theory must delve into the nuances of the timing of life events and crime to clarify both causal ordering issues and possible reciprocal effects of crime on the events themselves.

Finally, one important topic that is especially likely to be the source of future research is whether and how brain development during late adolescence and early adulthood plays a role in the timing and patterning of desistance. For example, the relevance of brain development can be seen in light of the role it played in the *Roper v. Simmons* (2005) US Supreme Court case that abolished the death penalty for juveniles. Given recent advances in brain imaging technologies and recent findings that the brain undergoes significant structural and functional changes during late adolescence and early adulthood,

especially in the prefrontal cortex area related to reasoning and impulse control, this topic is ripe for empirical investigation. This likely research on brain development will join the traditional social science literature along with the more recent interest in both biosocial and genetic explanations for explaining patterns of persistence and desistance among criminal offenders.

Abstract

The geography of crime has been recognized for a considerable time but has only in relatively recent years moved into a more central position as a significant part of criminology. There is a strong academic strand that has examined concepts such as crime areas and vulnerable areas and has developed theories to account for their existence in cities. These studies have drawn on geographical concepts such as the importance of place and the dynamics of spatial analysis but have also related to established social science benchmarks such as social disorganization and deviant subcultures. Additionally, a strong applied approach has developed that centers around the concept of geographical profiling and the application of techniques and algorithms of geographical information systems (GIS) to crime data.

Crime has its geographies and is a form of behavior that lends itself to the principles and methods of geographical analysis. Interestingly, the initial awareness of geographical crime patterns had a practical element; it was developed as an analysis with the potential for applications to problem solving. This applied aspect has become more and more predominant in recent times with the advent of procedures such as geographical crime profiling (the application of geographical information systems (GIS) techniques to crime data to allow the probable location of offenders to be identified. It can also be used to predict where offenses are most likely to occur) and the continued evolution of the family of techniques known as GIS (method for the collection and analysis of georeferenced data. It is now widely used by police forces in their use of crime statistics). Many government agencies and police forces now use crime mapping in its various forms as a standard tool in the task of criminal investigations. There are also what might be termed more 'academic' studies with no necessary practical outcomes but even they have the potential to contribute to the policy debate of understanding crime and criminals.

The recognition of crime patterns at a variety of scales can be traced to studies and reports completed in the early part of the nineteenth century. The geography of crime as a modern subdiscipline has moved from these identifications of patterns to their detailed representation, interpretation, and understanding. There are studies of the places where offenders live and the ways in which places that may be described as crime areas (those parts of the city that persistently suffer the most crime and tend to contain disproportionate numbers of offenders) emerge and persist. There are studies of the places that experience most crime and of the conditions that underpin their vulnerability. Different types of crime have different geographies and even the most simple forms of mapping will reveal these differences. Environmental criminology focuses on crime and place and has extended beyond an interest in the designed or built environment into the role of a more holistic concept of place. People experience crime and they also experience fear of crime and possible victimization, both of these affect their images of the environments in which they live. The neighborhood or residential area is one highly relevant environment and others include the places where they work or enjoy leisure and the 'pathways' they follow to reach such places. If some of the conditions that contribute to the incidence of crime in space, both real and perceived, can be identified, it is a short step to ameliorative policy formation. Criminology is a multidisciplinary field but it does now encompass a geographical perspective.

Crime is a form of deviance that involves the infringement of rules or laws that a specific society has created; both the act of a crime and the behavior of the criminal are therefore socially defined and those definitions will vary from one society to another and also over time within one society. A change in the law relating to drug abuse or traffic offenses, for example, will have significant impact on the geography of crime. The geographic study of crime draws a distinction between the geography of offenses, where crimes are committed, and the geography of offenders, where criminals live. As suggested, there are many different geographies of crime. The places where shoplifting, robbery, and residential burglary occur are all different: the teenage mugger is likely to come from a different kind of neighborhood than the corporate lawyer engaged in tax fraud. This diversity has stimulated study of the geography of crime at a variety of scales. Environmental criminology, with its focus on the places at which crimes occur, offers one organizing framework; the problematic concept of the 'crime area' offers another.

Origins

The origins of the geography of crime are found in early nineteenth century interest in cartographic criminology. A French statistician, Guerry (1833) who was employed in public service, produced maps showing the regional concentrations of crime. His observation that crimes of violence were disproportionately represented in the south of France led him to link criminal behavior and climate. In England, the social reformers such as Mayhew (1861–62) noted the strong clusters of crimes and criminals in specific areas of cities. Mayhew described the 'rookeries' of London where children were "born and bred to the business of crime." The Chicago studies of Shaw and McKay (1942) established a social science-based perspective on crime or delinquency areas, urban spatial patterns, and gradients and a set of 'theories,' principally Social Disorganization, that underpinned the ecology of crime in the city. Their studies gave

a strong impetus to an academic and theoretical analysis that had practical implications but also conceptual links to the evolving theories of the contemporary Chicago School of Social Ecology. The basic premises were that crime had a spatial order; it was not distributed randomly but showed strong and persistent trends to cluster in poorer, disadvantaged environments. Clifford Shaw moved from this analysis to found the Chicago Area Project aimed at helping youths in disadvantaged neighborhoods and this work has continued to the present day. Subsequent studies have shown a remarkable persistence of these basic qualities of a geography of crime and, further, have also demonstrated that spatial order, clustering, and a link with 'place' typify related aspects of the criminal justice system such as sentencing patterns. Policing policies and practices are other areas where these characteristics are evident and worthy of detailed study.

Information Bases

The geography of crime shares with criminology in general the problematic nature of the available data. Official crime statistics are suspect because the police record a relatively small minority of offenses that actually occur and apprehend an even smaller number of criminals. Approximately 80% of offenses never enter police records. This 'dark area' varies by type of offense. It is very high for offenses such as shoplifting or vandalism and low for car theft or homicide and arises from the unwillingness of the public, as victims or observers, to report crime to the police. Reasons for underreporting range from embarrassment to fear of reprisal to apathy. Police themselves actually observe few criminal events and therefore rely on the public, broadly defined, to notify them when offenses occur. Even the remaining 20% is further diminished by offenses not proceeded with. This underrecording of crime may mean that official data contains biases and deficiencies. Does it overrecord offenses by disadvantaged youths? Does it underrecord white-collar crime? Official crime statistics may reveal more about those who define criminality and administer the criminal justice system than about the actual incidence and seriousness of crime.

The official 'antidote' to these concerns about criminal statistics has been the introduction of national crime surveys. Dating in the main from the 1980s, these build upon an older ad hoc tradition of self-report studies and take the form of sample surveys of victimization experience and related attitudes toward crime, justice, law, and order. National crime surveys have confirmed underrecording and have qualified statements on rising crime rates, which may reflect differential recording practice rather than actual changes in crime. They have also augmented our knowledge of topics such as fear of crime. Whereas national crime surveys have not remedied the deficiencies of official criminal statistics, they have allowed for their interpretation in more refined and constructive ways. For geographers, official statistics and national crime surveys are useful for studies of national, regional, and local patterns of criminal activity and the quality of these databases are now well understood. There is continuing interest in identifying new historical data sources. The Bodleian Library at Oxford has a project to digitize records on crimes, murders, executions, and transportations in nineteenth-century England from the John Johnson Collection and provides links both to the Old Bailey proceedings web site and to sources at Harvard and Austin, Texas, in the United States.

Theoretical Bases

The geography of crime draws upon the generic theories of criminology and social science and its own disciplinary concepts. Criminology has nurtured many theories and a significant lack of consensus. Most embrace a 'multifactor' explanation, which, despite its diffuseness, is probably correct. There is no single causal explanation for criminality but a 'package' of interrelated conditions of varying applicability. Structural theories see criminal behavior as the inevitable outcome of societies that create inequalities. Yet these macro-theories fail to account for the fact that some individuals who suffer from inequality will react criminally, whereas others will not. Geographers have favored those criminological theories that lend themselves to analyses that allow a focus on place. Social disorganization is one such theory. Originating in the Chicago studies of the 1920s and 1930s, this theory linked crime with areas that lacked social order, established values, leaders, and social networks. Comparisons were made with residential areas that did possess these qualities, were 'socially organized,' and experienced low rates of crime. Subcultural theory, proposing that crime may be prevalent because it is part of the normal behavior pattern within specific groups, can be found in embryo form in Mayhew's study of London's rookeries. Although now argued most consistently in relation to social groups, subcultural theory can be articulated in terms of areas or neighborhoods. Social control theory shares common strands with social disorganization and subculture, emphasizing the positive impacts of social control mechanisms in reducing the incidence of criminal behavior. The mechanism may be good parental supervision, an effective school or teacher, or the effects of voluntary organizations or community groups. It is again a theory that can be adapted to a focus on place and has a central concern with the offenders and where they live.

Environmental criminology offers the closest approximation to a geographical 'theory' of crime. It emphasizes the criminal act and the location at which it occurs, the 'where' rather than the 'why' of crime (Bottoms, 1994). Place is central to an approach that acknowledges that each offense leaves a new point on the map and is a clue to the activity space of the offender. The approach draws in considerations of the routine spatial activities of offenders and victims, the concept of journey to crime, and related ideas of territoriality and surveillance. At the present time environmental criminology is more a methodology than a theory. As such it draws heavily on basic geographical concepts such as space and place, and lends itself to detailed spatial analysis through GIS. Conceptual issues include the problem of attaching any independent significance to space and understanding the full range of meanings attached to place, though these are issues that are generic to the study of human geography and are by no means specific to the geography of crime.

Approaches to the Geography of Crime

Studies that merit the description of a geography of crime have changed along with broader paradigm shifts within the social sciences. Cartographic criminology, basically concerned with the mapping of criminal statistics and the representation of spatial patterns, has evolved to reflect wider use of statistical methods including the sophisticated technology of GIS and will be discussed more fully in the next section.

The study of crime areas was an early focus for a geography of crime, arising from the persistent evidence that the mapping of both offenders and offenses revealed concentrations or clusters in space and indeed in disadvantaged neighborhoods. This evidence was apparent at a variety of geographical scales from regions to localities within cities but the most significant work arose from Shaw and McKay's studies of delinquency and crime areas in Chicago. There is persistent evidence for 'crime areas' and a simple exercise of mapping crime statistics makes this clear. Although crime areas can be identified in a reasonably clear way, the task of explaining their existence is less straightforward. Statistical analyses reveal strong correlations between the incidence of criminal residence and indicators of a poor residential environment. Measures such as high unemployment rate, low income, substandard housing, and low educational attainment recur and, less frequently, indicators such as lone-parent families and broken homes. Correlates of this kind have been interpreted as indicative of some more general condition such as social disorganization or weak social control, and particular significance is often attached to single measures such as high unemployment. For the most part, however, the results of this type of analysis remain descriptive; they have value in identifying groups and areas from which offenders are likely to come but are in effect markers of some more general social condition as is the crime rate itself.

Statistical analyses have also been used as a first stage in the study of crime or delinquency areas. After identifying clusters of offenders and the conditions under which they live, the research task then is to probe more deeply with different research methodologies into the nature of the 'crime area.' One approach has identified particular neighborhood characteristics that might predispose residents to criminology. Herbert (1976) compared 'crime' and 'non-crime' (or at least much less crime) areas in a city, controlling for sociodemographic profiles, and found a consistent difference in terms of sets of values and forms of behavior between the two types of area. In the 'crime' areas, parents adopted different approaches to control, had a clear tendency to accept some forms of misbehavior, and the children were lower achievers educationally. Other studies have examined this 'neighborhood effect' and the extent to which an individual's residential area has influence on criminal activity. The Edinburgh Study of Youth Transitions and Crime was a longitudinal study of the pathways into and out of offending for a cohort of 4328 children who started secondary school in the City of Edinburgh in 1998. One finding was that the characteristics of neighborhoods did play a role, albeit weaker than individual traits such as gender and personality, in influencing their delinquent and drug-taking behavior (McVie and Norris, 2006a). Delinquency and hard drug use were influenced by negative conditions such as high levels of deprivation. Another finding was that neighborhood effects were strongest in the earlier years of the cohort at around the age of 12 and became less significant as they became older (McVie and Norris, 2006b). Factors such as low social control and less social organization seemed relevant. Other neighborhood studies have focused on specific issues such as lack of parental supervision. More recently, what might be termed 'crime area' studies have taken a known problem area and sought to unravel both its origins and present form. In the United Kingdom, the so-called 'problem housing estates' lend themselves to this kind of analysis. Such estates often originated as local housing managers 'dumped' known problem families or relocated a slum clearance population to a specific estate. Early episodes of misbehavior reinforced labeling and reputations that have persisted. The Meadowell Study (Barke and Turnbull, 1992), based on an estate of around 2000 homes, demonstrated a lifestyle that was permeated by welfare dependency, drug-trading, petty crime, and vandalism. Often self-selection of tenants who opt for this kind of lifestyle builds the area profile. In late 1991, there were major riots and these events acted as a catalyst for change. Issues such as quality of housing, jobs, and local facilities were addressed with major changes to the physical environment. By mid-2000, significant improvements were being reported and Meadowell was being described as a well-cared for and thriving community (BBC, 2012). Crime areas change over time and as this example shows, they can be recovered by determined social intervention. There is also evidence that they are cyclical in the sense they are worse at specific points of local demographic change. The concept of a 'community career' suggests that some localities move through a form of life cycle with highs and lows of criminal activity (Bottoms et al., 1992). The impact of deprivation is far from removed from the concept of crime areas. Sections of urban populations are still being disenfranchised from the rest of society and the notion of a section of society that can be described as the 'truly disadvantaged' and the wider idea of an urban underclass exemplify this.

Understanding why criminal events occur where they do require different approaches. Criminals respond to opportunities or targets in the environment and the task is to identify these 'cues.' A large majority of such crimes are opportunist and involve minimal planning; a minority is 'professional,' involving experienced criminals who may spend significant amounts of time preparing for a single criminal event. It is the former that lends itself to analyses based on opportunism and environmental cues. What makes some areas or residential units more vulnerable to crime? First, areas that offer more obvious or lucrative targets for a crime such as burglary are often not likely to experience most offenses. In part this is a function of security, wealthier neighborhoods are able to defend themselves with security devices and forms of control such as block or neighborhood watch and gated communities. Research also shows that burglars tend not to travel far to commit an offense (Herbert and Hyde, 1985). The offender–residence hypothesis suggests that vulnerable areas are either the areas or are close to areas where offenders live.

Neighborhoods have 'cores' and 'borders' and the border-zone hypothesis suggests that the borders are more vulnerable. The local social control hypothesis suggests that ordered, well-organized neighborhoods with a strong sense of community identity experience less crime; the area variability hypothesis suggests that 'mixed' areas experience more. Hypotheses of these kinds, focusing on the places at which criminal events occur, blend into the general approach of environmental criminology. So too do studies of incivilities or signs of disorder in the urban environment (Herbert, 1993) and the idea that these may indicate a deteriorating situation in neighborhoods. The well-known study of 'broken windows' (Wilson and Kelling, 1982) instigated this line of thinking. Allied to the idea of vulnerable areas that suffer disproportionately from crime are studies of the movements of offenders, sometimes referred to as journeys to crime. There is ample evidence that the majority of offenders do not travel great distances to commit crimes and this is especially true of youths and opportunistic offending. Known areas are the favorite targets and these often correspond with the places and routes offenders travel in their normal everyday lives. For the small minority of professional criminals, the ranges can be much greater and involve planning and observation.

As criminals react to cues in the environment so do potential victims. Fear of crime arises from the perception that parts of the city, types of individuals or groups, and times of the day are dangerous and there is evidence for a steady increase in public anxiety about crime and safety (Smith, 2010). People will modify their behavior to cope with fear and to achieve feelings of community safety. Early studies identified residents' perceived stress areas and showed that these were avoided in everyday routines. Fear of crime is known to be high among old people and women with young children. Victimization experience and fear are linked to deprived areas but also to the routine forms of some urban lifestyles and specific demographic groups. Groups such as the elderly in fact experience less crime than youths but tend to adopt more comprehensive avoidance strategies to reduce risk. More broadly, studies of perceived 'dangerous places' suggest that feelings of fear are dynamic and contextual and are constantly being reassessed depending on factors such as time of day or night, past experiences, local knowledge, and presence of others (Lupton, 1999). Fear may often be stimulated by perceived disorders or negative cues (broken windows idea) in a neighborhood though Brunton-Smith (2011) argued that it was difficult to say which came first. Was it the perceived disorder that prompted fear or did fear lead to the perception of disorders?

Police have responded to evidence on fear and victimization studies with initiatives such as 'do not speak to strangers' to protect children, but part of the problem may lie in the design of city environments and conventional attitudes toward time and place. The step from environmental criminology to 'designing out crime' and crime prevention has proved a short one. In his thesis on 'defensible space,' Newman (1972) argued that places became more vulnerable if they had bad design features, lacked a sense of territoriality, had poor surveillance, and were stigmatized by their external images. If design could incorporate more positive qualities, it could create defensible space and become less vulnerable to crime. The most comprehensive test of defensible space principles was provided by Coleman's (1985) study of housing projects in inner London. She developed a 'disadvantagement' score that was made up of measures on a range of indices from presence or absence of overhead walkways to alignments of doors and windows. Coleman demonstrated close correlations of disadvantagement with crime and argued that less disadvantagement meant less crime. Although criticized for neglect of social dimensions, this work had a high impact on policy and on perceived community safety and quality of life. More restricted research designs, such as those to assess the impact of improved street lighting or CCTV camera surveillance, have produced similar positive results. The caveat with such measures is that instead of reducing crime they can simply displace it to other less well-protected areas. The ultimate in designing out crime is evident in rich suburban enclaves where high technology surveillance devices, walls, gates, and guards are used to protect residents. Davis (1990) wrote of fortress Los Angeles, divided between the protected enclaves of the very rich and the territories of the criminalized poor. Geographical research on social conditions also translates easily into crime prevention policies. Block or neighborhood watch is a direct transfer of ideas on community, surveillance, and social control. By mid-2000, 27% of British households (about 6 million) and 40% of the American population were participating in neighborhood watch schemes (Bennett et al., 2008). This analysis showed that there was sufficient evidence to state that neighborhood watch schemes are effective in reducing crime but that the processes that allow that reduction are not well understood.

The geography of crime has extended to consideration of policing, sentencing, and the criminal justice system. Early studies showed that sentencing was harsher in certain states and localities: the place where one committed a crime affected the sentence received. At international scale there are clear differences; Islamic law, for example, punishes an offense differently from European law. Within the United States, Florida tends to have more prisoners on death row and more executions (and Jury composition may affect verdicts) and in the United Kingdom, magistrates drawn from one class of society judge offenders from another. Policing as an activity has strong spatial connotations. Police carry images of the city, derived from their experience and passed-on wisdom; these influence the ways in which they police the city. As police patrol areas, they need a detailed understanding of those places; the distributions in space of offenders and offenses are key considerations for them. The police often focus their resources on specific areas and/or crimes for limited periods both in terms of community policing initiatives and crime prevention or target hardening. The policy known as 'zero tolerance' has been used to apparently good effect. Geographers have studied policing initiatives such as police consultative committees and the ways in which they are constructed. Studies of the so-called 'victimless crimes' of prostitution (Shumsky and Springer, 1981) suggest that policing practice and the variable workings of the criminal justice system shape their geographies. Vice areas emerged and changed within the city in response to varying policing strategies. Beyond policing

and the courts is the penal system, and as prison populations rise, their distribution and access are significant.

Applied Aspects of the Geography of Crime

Crime mapping has moved to higher levels of diagnostic investigation with the development of GIS and its application to crime data. GIS is a technology that is now available in many software packages and these can be customized to serve specific needs. There are generic packages such as Arc Info and Map Info that are widely used in teaching and research. GIS is designed to capture, store, and manipulate all kinds of geographical data and digitally creates integrated data systems. It allows us to view, understand, interpret, and visualize any georeferenced data, and this ability to display and identify relationships is a key quality. Police forces now recognize the value of GIS as a part of crime data analysis and the geocoding of criminal events for computer storage has become standard practice. There are clear advantages in the rapid portrayal of crime patterns and the related ability both to measure the features of the spatial pattern and to explore correlation with other environmental indicators. One police analysis of 79 crimes involving a single serial rapist was reported as involving 790 000 calculations using probabilities of journey to crime to link all points on a grid to the known crime sites (Grescoe, 1996).

Perhaps the clearest expression of the applied qualities of geography to the study of crime has been the emergence of geographic crime profiling. This approach uses quantitative models and algorithms of varying levels of sophistication to aid the process of criminal investigation. Data that show where a series of offenses have occurred form the input to a procedure that allows investigators to identify the likely locations or 'hot-spots' where the perpetrators of the offenses may be found. Awareness of geographic crime profiling has entered popular crime fiction. Val McDermid's novels revolve around a psychological profiler named Dr Tony Hill. In one of his investigations (McDermid, 2009) he calls in a Geographic Profiler, who uses an algorithm that he cannot understand, to help pin down the locale of the offender. Crime mapping not only identifies where the actual crime took place but also looks at where the perpetrators and the victims spend their normal lives. Therefore, where they live is of particular relevance and to a lesser, though still significant extent, the places where they work and spend leisure time. Most criminals operate within their 'comfort zone,' probably not far from where they live and in environments with which they are familiar. Simple geographic approaches such as centrographic techniques that allow comfort zones to be demarcated were early tools in this type of study. Neil Trainor, a police profiler at Bramshill College, spoke of the relevance of the principle of least effort to criminals; they work close to home, in places with the easiest access and least risk. Rossmo (1999) in his book titled *Geographic Profiling*, defines it as "an investigative methodology that uses the locations of a connected series of crimes to determine the most probable area of offender residence." As a police officer, he is clear that geographic profiling has an important supportive role when placed alongside the range of policing strategies. Among many other approaches, nongeographic crime profiling is a separate approach that continues to prove its value to many forms of criminal investigation. Yet, Porter (2010) notes that in 1996 the United States National Institute of Justice allocated $15 million to establish a crime mapping research center to promote crime mapping as an analytical tool and this center was renamed Mapping and Analysis for Public safety in 2002.

Underpinning the growth of geographic crime profiling has been the broader development and application of the methodology of GIS and its relevance to analysis of crime data. Haining and Ceccato (2010) have conducted many studies based on large georeferenced crime data sets from different countries. The methodology of all this work is quantitative using GIS and spatial modeling and includes studies of car theft and burglary in Stockholm and vandalism in Malmo. Some of this research is not driven by applied dimensions; studies of small area offense rates in the 'transition states' of Estonia, Latvia, and Lithuania, for example, were designed to test Durkheim's hypothesis that these political and social changes led to alienation and greater chance of criminality.

Future Directions

The geography of crime started from a few simple observations of spatial distributions and extended to a variety of applications of basic disciplinary concepts of space, place, and environment. Current thrusts involve developing pattern analysis through sophisticated information technologies, focusing on the meanings and relevance of place, and examining the interfaces between crime, criminals, and the criminal justice system. Clearly, the basic geographical approach of mapping crime in its various forms and expressions has become a prime focus of attention. Whereas there remain academic questions, such as the significance of place and neighborhood, the epidemiologies of criminal activity, fear and the experience of victims, and the applications of the criminal justice system including policing, the value of crime mapping as an investigative tool is a central concern.

Abstract

Despite much evidence to the contrary, the general public and policy makers in the US often assume that immigrants have higher crime rates than the native-born population and that the process of immigration itself increases the country's crime rates. In recent years, criminological researchers have produced many studies showing that the opposite might be true: immigrants are – on average – less involved in crime than the native-born population and the process of immigration has no or a negative effect on the national crime rate. In this article, we will highlight and summarize some of the existing research findings – both historical and contemporary – while at the same time pointing to areas in the field of immigration and crime that are much less understood to date. In addition, we provide a condensed overview of the existing knowledge on race and crime, and offer possible explanations for the overrepresentation of some ethnic and racial groups in the criminal justice system.

Members of the public and policy makers often assume a link between ethnic minorities, immigration, and crime, expecting rising immigration to produce greater crime and violence. In spite of these commonly held beliefs, there is a lot about the nature of the immigration and crime nexus that we do not yet fully understand. What we do know for certain is that among Western countries, *some* disadvantaged, minority groups tend to be overrepresented in arrests, convictions, and imprisonment (Tonry, 1997: p. 1). The affected groups differ in origin and characteristic across nations. In Canada and Australia, Aboriginal populations are disproportionately involved in the criminal justice system. In other places, this applies to recent immigrants (e.g., Moroccans in the Netherlands, Turks in Germany) and to visible ethnic/racial minorities (African-Americans in the United States, Afro-Caribbeans in England). Notably, the groups that face higher involvement in the justice system tend to also experience various forms of marginalization and disadvantage in their respective societies (e.g., in the educational system, in the formal economy, in access to health care, etc.). In spite of the disadvantage that visible minority and immigrant groups often face, *most* immigrant groups have lower crime rates than the native-born population.

One of the most important and least contested findings in contemporary research on immigration and crime is that broadly, immigration does *not* increase crime on the macro-level, especially violent crime, and may actually be associated with lower crime rates in neighborhoods (Butcher and Piehl, 1998; Kubrin and Trager, 2013; Reid et al., 2005; Rumbaut and Ewing, 2007). Even when "controlling for demographic and economic characteristics associated with higher crime rates, immigration either does not affect crime, or exerts a negative effect" (Reid et al., 2005: p. 775). This finding also holds for studies that put neighborhoods and cities at the center of their analysis (for a review see Ousey and Kubrin, 2009). Similarly important, research has consistently shown that first-generation immigrants are – on average – *less* likely to be involved in crime than their native-born counterparts. The observation that immigration is not associated with more crime but with less has now become the new intellectual canon (Lee and Martinez, 2009). Despite this, immigration policies in many US states have become more punitive in recent years (e.g., Arizona's SB1070, and similar laws in Winders, 2013), portraying the immigrant still as potential threat that needs to be controlled.

Overall, we need to acknowledge that the relationship between ethnicity, immigration, and crime is neither simple nor consistent across countries, and that we still have much to learn. For example, on the individual level, we need to better understand that the category of 'immigrant' is not a homogeneous one and factors like immigrants' ethnicity, age, gender, immigration history, family structure, and the quality of their reception in a host country make the study of immigration and crime complex and nuanced. On the neighborhood and city level, we still lack a good understanding as to why some immigrant neighborhoods are safer than others (Kubrin and Trager, 2013; Kubrin and Ishizawa, 2012). Lastly, our knowledge about immigrant victimization remains scarce (Stowell and DiPietro, 2013).

In this article, we will provide an overview of key issues that arise in the study of ethnicity, race, immigration, and crime, including definitional inconsistencies and challenges with cross-national comparisons. We will first offer some historical background on the immigration–crime nexus and present historical explanations that researchers and the public have used to explain linkages between immigration and crime. Subsequently, we will present empirical, contemporary findings on the immigration–crime nexus, including generational differences in offending. Further, we will turn to research on race, ethnicity and crime, present findings on ethnic or racialized discrepancy in victimization and crime rates in the United States and Canada, and will discuss potential areas of discriminatory treatment by the criminal justice system. Finally, we will identify some areas of research that we believe have been inadequately investigated to date.

Key Issues with the Study of Ethnicity, Race, Immigration, and Crime

Examining the links between immigration, race, ethnicity, and crime comes with certain challenges. For example, the concepts

of race and ethnicity are often conflated by researchers but are theoretically distinct. A common theoretical understanding of 'race' focuses on physical attributes, biology, genetics, and biologically induced behavior (Kalunta-Crumpton, 2012). 'Ethnicity' encompasses cultural traits, social interaction, nation-state, or place of origin and is related to the identity among those who share a set of cultural traits, histories, group dynamics, and experiences (Kalunta-Crumpton, 2012). Immigration usually refers to a legal status. These definitions are useful but do not rectify the difficulties in studying ethnicity, race, immigration, and crime. In practice, the distinction between race and ethnicity is often blurred or entirely ignored.

Another challenge is the difficulty of cross-national or cross-regional comparisons of empirical findings on ethnicity, race, immigration, and crime; it is imperative that contextual differences in each country or region are considered. Policies and standards for who are categorized as 'immigrant' or native born vary broadly across countries, making such comparisons ever more difficult. More importantly, there are not necessarily hard rules of definition in place. For example, in immigrant nations like the United States and Canada who are considered 'immigrant' and 'native born' are not automatically obvious: members of the second generation could be classified as 'native born' or 'second-generation immigrant' (Bucerius, 2011).

Elsewhere, statistics on immigration may be even more variable. Germany's official crime statistics only distinguish between German citizens and foreigners. Very restrictive immigration policies (like that of Germany) will likely result in many immigrants never gaining citizenship, whereas citizenship may be relatively quick to attain in countries like Canada. This makes cross-national comparisons difficult as the people categorized as 'immigrants' and 'native born' in each country are very different – making researchers literally compare 'apples' with 'oranges.' Additionally, crime statistics, definitions, and reporting practices are not consistent across borders.

Yet another difficulty for systematic cross-national comparison is that in most Western nations, justice statistics generally do not specify ethnicity and race of the offender because of the belief that collecting data on race and ethnicity would violate civil rights or incriminate certain ethnic or racial groups. More recently, many minority groups who were previously opposed to the collection of race-based statistics now advocate their collection as a means to "redress racial discrimination in the administration of justice" (Owusu-Bempah and Millar, 2010: p. 97). The United States and the United Kingdom stand alone among Western countries in their collection of race and ethnicity in crime data. Still, census and crime data collected in the United States include only broad racial categories (black, white, Asian, American/Alaskan Indian, Pacific Islander) that do not acknowledge ethnic differences, conflating the experiences of immigrants from very different cultural backgrounds and migration histories on the basis of skin color. Ultimately, we would argue that using the category of 'ethnicity' would provide a much more nuanced and detailed analysis than 'race.'

Another key issue in relation to studying immigration, ethnicity, race, and crime relates to age and gender, as they are frequently identified as the chief predictors of criminal involvement in the criminological literature. Young males have a higher propensity for criminal behavior. In his look at the relationship of immigration and crime in the United States, Waters (1999) found that during large immigration waves, immigrant groups were disproportionately young males (as cited in Bucerius, 2011: p. 389). Since recent immigrants are still disproportionately young and male, it is critical that researchers control for age and sex when attempting to discern a connection between immigration and crime (Bucerius, 2011). Similarly important is to keep in mind that most studies solely focus on the relationship of violent crime and immigration (Martinez and Lee, 2000; Lee and Martinez, 2002; Martinez, 2002; Feldmeyer, 2009; Stowell et al., 2009), ignoring other types of criminal activity.

Aside from age and sex differences, immigrants' ethnic and socioeconomic backgrounds and reasons for immigrating must be considered. Recent immigrants are a diverse group, and these factors may be salient in the study of an immigration–crime nexus. Likewise, there are significant generational differences in criminal involvement among immigrants. In Western countries, second-generation immigrants typically have higher crime rates relative to their first-generation counterparts. The second-generation crime rates relative to the native-born population differ across countries. For example, on average, second-generation immigrant groups in Canada and the US tend to have lower crime rates than the native-born population. In Europe, some second-generation immigrant group crime rates exceed those of the native born.

Lastly, studies about the relationship of immigration and crime are often insensitive to differences within the 'immigrant' category. Most do not (or cannot) distinguish between legal and illegal immigrants, partially because reliable estimates for the number of undocumented immigrants are not available. Estimates for the number of undocumented immigrants in the United States fluctuate by millions (Bucerius, 2011), and equivocal claims for their tendency to engage in crime are possible. In line with economic (Becker, 1968; Ehrlich, 1973) and strain theories (Merton, 1938; Cloward and Ohlin, 1960), immigrants with limited, legitimate economic opportunities may be expected to resort to criminal activity. Early work has emphasized the 'difficulties of adjustment' (Taft, 1933) to explain immigrant crime. Conversely, it can be argued that their vulnerable (illegal) status makes undocumented immigrants eager to avoid contact with law enforcement.

Overall there are many peculiarities and limitations that the reader needs to keep in mind when looking at research on immigration, ethnicity, race, and crime, and many research questions that remain relatively understudied. Below, we will first turn to historical and contemporary research on immigration and crime and then turn to research on race, ethnicity, and crime.

Immigration and Crime

Historical Background on Immigration and Crime

The notion of a 'criminal immigrant' appearing in the media, political discourse, and public opinion is not new. During the mass immigration of Eastern Europeans to America at the turn of the twentieth century, concern about immigrants contributing to social problems, like crime, was great (Reid et al., 2005). In response, legislation to hamper or stop certain

immigrants from entering the United States was introduced (Hagan and Palloni, 1999). Concern about immigration and crime declined after the Second World War when the US economy was strong. Recently, public attitudes have shifted once more. Indeed, from the recent General Social Survey, nearly three quarters of Americans believe immigration and higher crime rates are positively correlated (Rumbaut and Ewing, 2007; Feldmeyer, 2009: p. 718). These concerns are triggered by and exacerbated in response to immigration influxes and crises (e.g., the 9/11 terrorist attacks in the United States).

Historically, a series of federal commissions in the United States (the US Industrial Commission in 1901; the 1911 Immigration Commission; and the 1931 National Commission on Law Observance and Enforcement) tried to shed light on the immigration and crime relationship. The 1901 Industrial Commission used prison statistics as a measure of criminality and found foreign-born whites were less criminal than native-born whites (Industrial Commission, 1901). Because the native-born prison population was composed of a large number of second-generation immigrants, these findings were interpreted as supporting the 'injurious effect of immigration' (Industrial Commission 1901 in Tonry, 1997: p. 20). The 1911 Immigration Commission had similar aims but divergent interpretations from the earlier Industrial Commission. The commission concluded that immigration did not increase crime significantly or at all. The 1931 National Commission on Law Observance and Enforcement used crime and arrest statistics and found first-generation immigrants proportionately committed fewer major offenses than native-born persons of the same age and sex. In an effort to measure the criminal involvement of the second-generation, the commission interviewed criminal justice officials and concluded that the 'immigrant crime problem' was not due to immigrants 'but to their sons' (Tonry, 1997: p. 20).

Early academic work sometimes relied on biological explanations to account for immigrant crime, purporting that immigrants were biologically inferior to nonimmigrants (Martinez and Lee, 2000: p. 488). These explanations have been discredited as racist and lacking empirical and theoretical value (Gabor and Roberts, 1990; Wortley, 2003). Researchers have also attributed cultural differences to explain differences in crime rates between ethnic and racial groups (Taft, 1933; Sellin, 1938; Hawkins, 1994; Erlanger, 1995). Similar to biological explanations, cultural approaches have been criticized by academics for failing to explain nonimmigrant offending (Bucerius, 2011).

A historical examination that still holds much value in contemporary research goes back to Edwin Sutherland's (1924) criminological examination of immigration and crime, which found that immigrants in the United States engage in crime less than the native born. Sutherland found first-generation immigrants had, on average, lower crime rates than subsequent generations. As well, those who immigrated to the United States as children were more likely to be later incarcerated than those who immigrated as adults. According to Sutherland, immigrant criminal involvement increased with time spent in the United States and with later generations – a finding that still holds true in most empirical studies today. He identified that acculturation, and not immigration itself, were to be blamed for increased incarceration and arrest. In other words, the more Americanized immigrants became, the more their crime rates resembled the (on average, higher) crime rates of native-born Americans.

Contemporary Empirical Findings on Crime and Immigration

Discussions of an immigration–crime nexus frequently center on immigrants' involvement in crime or on the influence of immigration on crime. If something intrinsic to immigration produced a greater proclivity for criminal offending, countries and cities with higher immigration rates should have elevated crime rates. That is to say, universally, immigrants should offend more often than native born. Most scholarly work on immigration and crime has debunked this supposition (Reid et al., 2005; Ousey and Kubrin, 2009; Stowell et al., 2009).

Contemporary studies at the individual level repeatedly indicate that immigrants have lower offense, arrest, or incarceration rates than the native-born population (Bucerius, 2011). There is a dearth of statistics in this area looking at ethnic group differences and immigration status, save for incarceration data (McDonald, 1997). Using incarceration rates as a proxy for offending is problematic since immigrants are at greater risk of incarceration than native born (Hagan and Palloni, 1999). In spite of this disproportionate risk, in actuality, immigrants are less likely to be incarcerated than the native-born population. Butcher and Piehl (2007) analyzed census data over 1980–2000 and found the native-born population was more likely to be institutionalized (incarcerated) than immigrants. They concluded the process of immigration selects individuals who are more amenable to deterrence. Similarly, Rumbaut and Ewing (2007) found the foreign-born immigrants in the United States were less likely to be incarcerated than the native-born population. This pattern was found for all ethnic groups.

The existing studies on the effect of immigration on aggregate criminal offending provide support that immigration does not increase, and may even reduce, violent crime rates (Butcher and Piehl, 1998; Hagan and Palloni, 1999; Lee et al., 2001; Martinez, 2002; Reid et al., 2005; Ousey and Kubrin, 2009; Stowell et al., 2009). Most notably, research by Sampson across 180 communities in Chicago has shown that concentrated immigration predicted lower rates of violence, with the relationship strongest in poor neighborhoods. Sampson argues in a now-famous New York Times Op-Ed that immigration not only appears to be 'protective' against violence in poverty areas, but that immigration as a whole might have been responsible for the overall crime drop in the United States in the 1990s (Sampson, 2006).

To date, we know much less about the victimization of immigrants. Stowell and DiPietro's (2013) descriptive examination of immigrant victimization reveals that foreign-born individuals (i.e., first-generation immigrants) have a slightly higher homicide risk than their native-born counterparts; with Latino immigrants having the highest risk of homicide victimization among the ethnic groups in their analysis. However, homicide victimization rates for immigrants falls more quickly than for native-born individuals.

While research in the US context has debunked the idea that immigrants are more criminal than the native born and that

immigration leads to elevated crime rates, the picture is not as clear in the European context, with some disadvantaged minority groups being disproportionally involved in the criminal justice system. Is it important to avoid reductionist explanations of the role immigrant status and ethnicity play in criminal involvement and justice system experiences. Tonry (1997) advises that not all economically and socially disadvantaged groups are disproportionately involved in the criminal justice system. For example, despite arriving in England and Wales during the same time period and being subject to comparable forms and levels of discrimination, Afro-Caribbean and Indian migrants' involvement in the justice system are extremely dissimilar (Tonry, 1997: p. 2). Similarly, the experiences of Moroccans and Turks in the Netherlands are also divergent, in spite of similar economic and social disadvantage (Moroccans, but not Turks, have much higher crime and incarceration rates than the Dutch population) (Tonry, 1997; Junger-Tas, 1997; van Gemert, 1998). Meanwhile, although Dutch Turks and German Turks share similar migration histories and socioeconomic backgrounds, the incarceration rate for Turks in Germany is much higher than the native population (Koopmans, 2003). We believe that immigrant incorporation strategies and discrimination against certain immigrant and/or ethnic groups in different countries significantly contribute to the overrepresentation of ethnic groups in some countries but not others (see also Martinez and Stowell, 2012).

Generational Differences

The acculturation thesis described by Sutherland remains relevant and supported by many studies on generational differences (for an overview on generational differences, see Berardi and Bucerius, 2013). In spite of improved conditions relative to the first-generation, second-generation immigrants tend to fare more poorly with regard to crime rates (see Berardi and Bucerius, 2013; Picot and Hou, 2011; Portes and Fernandez-Kelly, 2008; Rumbaut and Ewing, 2007). This downward trend may be partly explained by the process of acculturation. Rumbaut and Ewing (2007) describe a 'paradox of assimilation.' The process of assimilation is often touted as a positive transformation for immigrants (e.g., gaining English language proficiency, education, job skills) that facilitates their settlement and eventual success in the economy and society of the host country. Ironically, assimilation appears to have a sinister aspect as well. Immigrants' criminal behavior and health status worsen and mimic those of the native-born population. Mirroring Sutherland's findings, second- and third-generation immigrants have greater risk of incarceration relative to the first generation. First-generation immigrants' risk of incarceration also increases along with their stay in the United States.

In a longitudinal study of neighborhood in Chicago from 1995 to 2002, first-generation immigrants of several racial and ethnic groups were nearly 50% less likely to violently offend than third-generation comparators (Sampson et al., 2005). As would be expected from the acculturation thesis, second-generation immigrants were more likely to commit violent crime than the first generation, but less likely than the third generation. Racial group differences observed between black and whites could also be explained by immigrant status, which was identified as a protective factor against violence. For example, whites in the study were more likely to be recent immigrants than blacks, and blacks demonstrated increased violent crimes. Controlling for immigrant generational status, the disparity in violence shrunk. The limited research on immigrant involvement in delinquency and substance abuse in the United States is fairly consistent with research findings on violence – first-generation immigrants tend to be less likely delinquent or use illicit drugs than the second generation (see examples, Vega et al., 1993; Bui, 2009; Gfroerer and Tan, 2003).

Exceptionally, second-generation Asian-Americans are less likely than the first generation to commit homicide, suggesting that they might also score lower on other types of crime in comparison to their parents' generation. Factors like cultural norms, parental oversight, and structural forces may account for the success achieved by Asian immigrants in academics and crime avoidance; the so-called 'Asian advantage' (Zhou and Kim, 2006; Min and Kim, 2009) has been used to explain why second-generation immigrants of Asian heritage tend to outperform other immigrant and native-born populations academically.

The trend for first-generation immigrants to be less violent and involved in crime than native born and subsequent generations is generally true for most ethnic groups in the United States. First-generation immigrants who consciously choose to immigrate to a new country may be more dedicated to succeed in the new country and prepared to defer short-term gratification (which crime might offer) with this objective in mind (Berardi and Bucerius, 2013). First-generation immigrants attribute their experiences of exclusion as exceptional and the fault of individuals (Viruell-Fuentes, 2007). Subsequent generations of immigrants seem to be more affected by experiences of exclusion than the first generation and more readily identify these incidents as evidence of systemic discrimination and social exclusion (Bucerius, 2011).

Another explanation could be that first-generation immigrants compare their living situation in the host country to their country of origin. The second generation may refer to a different comparator – the native born. Having no (or limited) exposure to their parents' country of origin, the second-generation immigrants may suffer more by the unequal distribution of opportunities. Feelings of deprivation may propel the second generation to innovate ways to achieve successes that are precluded for them (Merton, 1938). While these explanations offer some insight into the generational increase in crime rates, they cannot fully account for the relationship of generation and offending; some second-generation immigrants do not show elevated crime rates. Additional factors such as opportunity structures (Engbersen et al., 2007), family structure (Portes and Zhou, 1993; Portes and Rumbaut, 2001), and neighborhood (Shaw and McKay, 1969) may also be impactful.

Countries with immigrant incorporation policies that promote integration can reduce the likelihood of immigrants becoming involved in crime. Research from Sweden shows that the country's inclusive immigration policies help reduce second-generation offending (Bucerius, 2011). Specifically, studies have shown that second-generation immigrants

experience disadvantage and exclusion in education (Portes and Rumbaut, 2001; Farley and Alba, 2002; Bucerius, 2009), suggesting that the school system is one important area in which carefully considered incorporation policies can make a significant difference (Bucerius, 2009). Telles and Ortiz (2008), for example, demonstrated that Mexican immigrants have faced systemic exclusion for multiple generations in the United States and suggest that this group could benefit from attention. Dinovitzer et al. (2009) also attributed education as being protective against criminal involvement for certain immigrant groups. Subsequently, some researchers have recommended that policy makers aiming to reduce immigrant crime redirect their attention to bridging the educational gap between second-generation immigrants and nonimmigrants.

Ethnicity, Race, and Crime: Discrimination and Disparity

The US Context

The relationship of race and crime has long interested American scholars and policy makers. Arrest and incarceration data from the United States has consistently shown that blacks tend to be overrepresented as offenders and inmates, while Asians are particularly underrepresented. Uniform Crime Reports ('UCR') from the United States provide some insight to the race of offenders and victims but only capture crimes that are reported or where an offender was identified and arrested. In 2011, the UCR indicated that 69.2% of arrests in the United States were whites, whereas blacks represented 28.4% of the arrests (FBI, 2011). Meanwhile, census data from the same period estimates that around 13% of the general population is black (US Census Bureau, 2012), pointing to an overrepresentation of blacks in the criminal justice system. Importantly, in addition to racial categories, the UCR distinguishes between two ethnic categories: Hispanic and Non-Hispanic. Hispanics, as the largest minority group in the United States, can be captured in different racial categories (i.e., Hispanic offenders can be classified as white or black). As of 2013, the Hispanic category will be changed to 'Hispanic and Latino origin.'

Similarly to the UCR, the National Crime Victimization Survey, looking at violent crime, property crime, and personal theft, indicates not only an overrepresentation of blacks in arrests but also with respect to victimization. From the 2009 survey, for example, blacks were more likely than whites to be victims of violent crime. While there was no significant difference in the likelihood of Hispanics and non-Hispanics to experience violent crime (including rape, sexual assault, and assault), Hispanics were more likely to be victims of robbery. Native-American women had higher rates of victimization for rape and sexual assault than white or black women (Kalunta-Crumpton and Eijogu, 2012).

Canada

Canada's international reputation as a diverse and tolerant nation has not protected it from moral panics prompted by minority criminality nor is its criminal justice system free of discrimination toward certain racial minorities (Wortley and Owusu-Bempah, 2012). Since official race–crime statistics are not released in Canada, it is difficult to produce an accurate account of the victimization and offending experiences of racial and ethnic minorities. In 2004, Canada's General Social Survey (a national, random sample survey) found no significant difference among visible minorities and whites with regard to property and violent victimization. This may be because the aggregate 'visible minority' category failed to distinguish between racial and ethnic groups (Wortley and Owusu-Bempah, 2012: p. 15).

Like in the United States, some studies in the Canadian context have shown that certain ethnic groups are overrepresented as victims of crime. While much of the discussion on overrepresentation in the US centers on blacks, much of the focus in the Canadian context lies on the overrepresentation of Aboriginals (both with respect to offending and victimization). Nationally, the homicide victimization rate of Aboriginal people is up to eight times that of non-Aboriginals (Brzozowski et al., 2006). Serious violence in large Canadian cities is also disproportionately concentrated in the black community (though to a lesser extent than in the Aboriginal community), and the homicide victimization rate for blacks in Toronto was four times the city average (Gartner and Thompson, 2004). Black males are overrepresented as homicide victims (4% of the city population, but 40% of homicide victims) (Wortley, 2008).

While census and federal correctional data suggest that Aboriginal and blacks are grossly overrepresented in the Canadian prison system, the representation varies across regions (Wortley and Owusu-Bempah, 2012: p. 17) and attempts to explain this discrepancy are made more difficult by the dearth of relevant statistics. Some research indicates that both overrepresented groups (black and Aboriginal people) *may* commit certain types of crimes more often than other racial groups, but this is inconclusive and their different rates of offending (especially for street-level crime and violence) can be explained by socioeconomic disadvantage (Wortley and Owusu-Bempah, 2012).

Possible Explanations for Overrepresentations

A potential explanation for racialized differences in victimization could be the intersection between race and class. Much criminological research has shown that most crimes are intragroup offenses; i.e., the offender and victim often come from the same ethnic background. Moreover, persons with lower income are more at risk of property and violent crime than those with high incomes, particularly for persons who are not of Asian origin. For example, blacks in low-income households face greater risk of violence than those in higher income households (Kalunta-Crumpton and Eijogu, 2012: p. 50). Racialized minorities still tend to occupy the more marginalized positions in society. In other words: they are more likely to be classified as low income, and thus, face a higher risk of both criminalization and victimization.

Aside from observed differences in the offending and victimization of certain ethnic minorities, these groups are also subject to differential treatment by the criminal justice system as a consequence of systemic disadvantage or more overt forms of racism. Decisions made in the criminal process that seem innocuous and neutral can contribute to the systemic

disadvantage of members of certain minority groups. For example, the decision to detain someone before trial, even when ostensibly based on an accused person's stability or likelihood to appear, can disadvantage minority groups who are more likely to be low income, unemployed, or lack a permanent residence (Tonry, 2011: p. 16). These disparities early in criminal proceedings have a cumulative effect; persons detained before trial are more likely to be incarcerated after trial. Studies on pretrial detention have been performed in the United States, Canada, and Europe (see Tonry, 2011 for more extensive coverage).

A popular example of racism in official crime policy is the differences in sentencing for crack cocaine vs powder cocaine charges in the United States. Crack cocaine, associated with low income, racialized users, is associated with much harsher sentences than the more expensive powder cocaine. Another area of contention are 'three strikes' laws that impose significantly lengthier sentences for third offenses. Some have argued that these laws unfairly impact blacks in the United States because of their overrepresentation in violent crime (Tonry, 2011). The continued use of the death penalty in certain American states has also been criticized as biased toward black offenders (Zeisel, 1981). In the Canadian context, racial profiling by the police and biased treatment in the criminal justice system (e.g., in sentencing, pretrial detention decisions, police use of force) also unevenly impacts certain groups. A study from Kingston, Ontario analyzed police stops and found black residents were three times more likely to be stopped than whites, and the difference in stop rates could not be explained by age, gender, location, or reason of the stop (Wortley and Marshall, 2005).

While racial profiling and disparities at the pretrial and sentencing stage may partly explain the overrepresentation of racialized minorities in certain crimes, there is still much to learn with respect to the degree in which these factors play a role and to what degree with need to turn to other structural forces (such as income disparities, segregation, historical and contemporary racism, etc.). One consequence of differential treatment in the criminal justice system and racial profiling is that it may further alienate communities who are already distrustful of the state and the police by confirming suspicions of discriminatory practices.

Crime in the Rural Context

Joseph F Donnermeyer, School of Environment and Natural Resources, The Ohio State University, Columbus, OH, USA

Abstract

The study of crime in a rural context, or rural criminology, is advancing rapidly, even though it was slow to develop during much of the twentieth century. This article addresses five key areas within rural criminology, including agricultural crime, environmental crime, drugs, violence, and rural communities and crime. The literature in each area is reviewed, and implications of rural crime scholarship for criminological theory are noted, especially for how this research reveals fallacies and suggests revisions to place-based theories and concepts like social disorganization theory and collective efficacy. This article on crime in a rural context is not comprehensive, however, but observes that there are substantial bodies of literature on issues associated with hate crime and hate groups, crime at rural-located parks, recreation areas, tourist sites, and other public places, gangs, other forms of organized crime, and issues associated with policing, courts, jails, and other infrastructural aspects of the criminal justice system.

Introduction

Until very recently, the world's population was a majority rural population. Even though it was estimated that this would change sometime during 2008 (for the first time in human history), the percentage of people who reside somewhere other than cities and suburbs will remain a significant share of all people who live on this planet for quite some time (Population Reference Bureau, 2007). In 2015, about 3.36 billion (48.1%) individuals were estimated to be rural, and rural people will exceed 3 billion throughout the first half of the twenty-first century, even though the non-urban share of the world population will decline to about 33% (Department of Economic and Social Affairs, United Nations, 2012).

Even in highly urbanized countries like Australia, Canada, Great Britain, and the USA, where so much of criminological scholarship is focused, rural people are a significant share of the citizenry. For example, in the USA, about one in six residents live in areas defined as rural, according to the US Bureau of the Census (2012). This represents an astonishing 52 plus million individuals, which exceeds the total populations of countries like Kenya, South Korea, Spain, and Ukraine, and nearly equal to the population of South Africa. If the US rural population was a 'stand alone' country, its size would rank it as about the 26th most populous. Likewise, rural people compose about 10% of all Australians, nearly 19% of Canada's inhabitants, and 20% of people who live in the UK (Department of Economic and Social Affairs, United Nations, 2012).

Even though a great many of these rural people live within easy driving distance of large, urban centers, it remains true that despite a continuing transformation of the world from rural and agricultural to urban and industrial/postindustrial, crime in the rural context is important for understanding crime in general. Yet, the criminological communities in these four countries, and most other regions of the world, have virtually ignored rural crime; that is, until recently.

It is indeed ironic that the strongly held urban bias of criminology arose during the very time when these countries were still majority rural societies, and when accounts of highway robbery and frontier outlaws were closer in time than today. The second irony is that during the past three decades, when the urban transformation of the world has continued at an unerring pace, rural criminology as a specialization within criminology has begun to emerge (Dingwall and Moody, 1999; Hogg and Carrington, 2006; Donnermeyer and DeKeseredy, 2014).

Rural Crime

Perhaps one reason that rural crime was ignored in the past by criminologists is the difficulty in defining and specifying what constitutes rural. Certainly, where census or population data is available, criteria for defining rural can be clear, although the definitions vary from country to country. As well, within a single country like the USA, there are multiple definitions of rural, even though the two most popular are: (1) a traditional census definition of rural as any place with less than 2500 people that is not contiguous to a larger, urban locality; and (2) 'rural' counties that are defined as either micropolitan (with a place larger than 10 000 persons but no bigger than 50 000) and non-metropolitan (without a place larger than 10 000 inhabitants) (US Bureau of the Census, 2010). Hence, cross-county comparative statistics on official rates of crime and arrests between rural and urban places becomes problematic, both empirically and conceptually.

Another layer of complexity lies in interpretation of the statistics, since it can be argued that there is an inherent bias in police records that belie objective comparisons because of the generally larger per capita presence of police in urban communities, hence, rendering the higher rates so often found for urban crime as an artifact of the reporting system itself (Maltz and Targonski, 2002). In short, where there are more police, there will be more reported crime.

A second reason is the nearly impossible task of differentiating clearly the generalizing features of rural places from urban places. In particular, the growth and spread of electronic media and the rise of mass society complicates further the sociological differences of rural from urban. Since the establishment of the Chicago School of Sociology in the first third of the twentieth

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45049-X

century and the publication of the still frequently cited work of Louis Wirth (1938) on 'Urbanism as a Way of Life,' coupled with the proportionate size of the urban population in countries where criminology is the most highly developed and where the official statistics suggest a higher rate of crime for urban places, rural was mostly ignored.

The problem is that many criminologists confuse what rural means, and by extension, what urban means. Many fall back on simplistic dichotomies which conflate the geography of 'space' with the economic, cultural and sociological characteristics of 'place' (Liepins, 2000). The most famous of these dichotomies is the well-known distinction by Tonnies – gemeinschaft vs gesellshaft – with the former representing in the minds of many mainstream criminologists the concepts of rurality, cohesive places, high levels of collective efficacy, and relatively little crime; and the latter linked to urbanity, social disorganization, and relatively more crime. Today, a concept like collective efficacy, which means "social cohesion combined with shard expectation" is given a one-dimensional treatment; that is, it must only be associated with less crime (Sampson, 2012, p. 27).

Another conceptual fallacy is made by criminologists who attempt to define rural and urban distinctions based on theories and concepts of social change (Donnermeyer, 2012). Hence, rural comes to mean preindustrial, agrarian, small, 'folk'-oriented groups with mechanical solidarity and urban depicts industrial/postindustrial, and large-scale forms of social organization with organic solidarity.

The rural (and urban) reality is that in order to advance criminological thought, dichotomies should be replaced by more complex conceptualizations that start with a geographically-based definition of rural, and by extension, urban. Specifically, rural places have smaller populations and/or population densities, and this is perhaps the only difference between rural and urban spaces common across the spectrum of developed and developing societies. The real point is that the specific social organizational, cultural, and economic profile of rural areas varies as greatly as do the specific characteristics of urban neighborhoods. Hence, crime varies as well. For example, rates of robbery, according to the FBI's (2012) *Uniform Crime Reports*, is many times lower at rural places when compared to urban localities, but the percentage of burglaries experienced by farmers may be higher than all but a few urban neighborhoods (Barclay and Donnermeyer, 2007). Hence, from this point of view, what the field of criminology has actually ignored is the evidence of expressions of crime at smaller places, and by doing so, fails to establish a more generalized validity to criminological theories like social disorganization, and frequently cited concepts, like collective efficacy. Even though the rural world is shrinking proportionately, it still represents a significant share of the population of both developed and developing countries, and criminology cannot pretend to have valid theories if it cannot make these theories work outside of an urban context.

There are five areas where the rural criminology literature has focused most keenly in recent times. Each describes a rural reality different from anything assumed by dichotomous thinking and simplistic theorizing. They include: agricultural crime, environmental crime, drugs, violence, and rural communities and crime.

Agricultural Crime

The industrialization of farming in advanced capitalist countries has had two concurrent consequences. First, the proportion of the population which lives on a farm has declined to such an extent, that in a country like the USA, less than 2% of its residents are directly involved in commercially grown/raised food (even though there are many more people who have food gardens in their backyards or raise some livestock part-time, perhaps as a hobby/leisure pursuit). Second, to maintain efficiency in food production under globalized market conditions requires a huge economic investment in machinery, equipment, and supplies.

Even though 'rustling' livestock forms a romanticized part of the frontier lore in Australia, Canada, the USA, and other places, few systematic studies of agricultural crime have ever been conducted. However, those that have been completed paint a picture of extensive victimization experienced by agriculturalists. Research from Australia, the UK, the USA (Barclay and Donnermeyer, 2011), and the east African country of Kenya (Bunei et al., 2013), show annual rates of victimization as follows: for machinery and equipment theft – 10–25%; for burglary – 6–12%; for theft of farm animals – 1–13%; and for vandalism – 13–24%. The wide range (ratio of low to high estimate) of animal theft is partly explained by the type of agricultural operations that occupy an area, which in turn, depends partly on climate and topography. Some areas are mostly devoted to crops and vegetables, while other localities are predominately dedicated to livestock. In these latter areas, the theft of animals can be much more extensive.

Some farm crime may be the case of a food producer whose livestock is stolen by a neighbor who is also a farmer, as Barclay (2003) found in her study of agricultural victimization in New South Wales. Also remarkable in Barclay's (2003) research was the pressure on the farmer-victims to not inform the police ('dob in') about their neighbors-as-suspects, which is contradictory to the notion that cohesive rural communities where everyone knows everyone else form the conditions under which crime is restrained or controlled. Simply put, in smaller groups, in this case, smaller communities, one faces ostracization for snitching. Second, the research indicates that forms of violent crime victimization (with one exception) are low to nearly nonexistent for food producers (Barclay and Donnermeyer, 2011). The exception (discussed below) is domestic violence: that is, how various economic and social forces related to farming facilitate abuse of farm women by their partners (Carrington et al., 2013).

There are no reliably accurate estimates of the economic costs of agricultural crime. However, Swanson et al. (2002) suggested losses to agriculturalists in the USA alone from crime at about $5 billion annually. More recently, Mears et al. (2007) estimated both high rates of victimization and over $10 million in stolen property annually for a single nine-county area of central California. The list of items stolen is remarkably diverse, but all of the property had economic value and could be converted to cash, including scrap metal, barbwire, saddles and tack, irrigation pipe, water pumps, diesel fuel, beef cattle and other farm animals, nearly ripened fruit from groves of trees and bushes, chemicals, and welders. Echoing these claims is a survey of farmers in Hawaii by the National Agricultural Statistics Service of the US Department of

Agriculture, which found an overall victimization rate to agricultural operations of 17% and a total dollar cost equivalent to 3% of net farm income, plus another 6% for the cost of security (NASS, 2005).

The extant criminological literature on agricultural victimization, especially the work by Mears et al. (2007), demonstrates the relationship between social change and crime. There are two primary factors that explain why farm crime should be taken seriously, both of which are commensurate with routine activities theory (Barclay and Donnermeyer, 2011). First, the industrialization of agriculture in many parts of the world has made farm property increasingly attractive for theft. Simply put, if the property is valuable and can be liquidated for cash, it stands a greater chance of being stolen. Second, as the number of farms in many parts of the world has declined in response to the industrialization of agriculture, the size of farms has increased. Hence, the physical or geographic distribution of farm property is spread out in ways that make it difficult for the agriculturalist, other family members, and even farm employees/laborers to maintain a natural form of surveillance, that is, as they go about their daily routines. The consequence is an increase in opportunities for crime as guardianship declines with farm size.

Environmental Crime

One of the fastest growing specializations in criminology is the study of environmental crime, which has come to be known as 'Green Criminology.' The adoption of the moniker 'Green Criminology' also expands the scope of meaning of criminological scholarship to include not only actions by individuals, corporations, and states which violate the law, but actions which harm peoples and communities through environmental degradation and threatened livelihoods (White, 2009; South and Brisman, 2013).

Rural criminology is at its core place based, hence, a great deal of environmental crime can also be regarded as rural crime; or, in cases of transnational networks for the illegal smuggling of flora and fauna, as equally rural as urban in context. For example, illegal logging is a rural located crime, but with obvious urban linkages and connections to other forms of crime as well. A recent news story describing the poaching of redwoods in northern California illustrates this connection. The trees are stripped of their burls and other knotty wood by thieves who sell the pieces for money. Burls can fetch over $2 a pound, and a redwood table on E-Bay can be worth $1000 plus. One law enforcement officer who has interviewed those apprehended for the offense indicated that most said they use the money to support their drug habits (Graham, 2014). McSweeney et al. (2014) note that clandestine drug operations in central America have tipped the balance of nature to such an extent that whole swaths of rain forest are destroyed or denuded, which has rippled through the natural ecology of the region, affecting other plants and animals as well, plus the people who live there. Also common are logging companies who violate state and national laws regulating tree harvesting, and in many parts of the world, harvest rare and endangered tree varieties, and often trespass in preserves, national parks, and protected areas to find valuable wood for sale on world markets (Green et al., 2009).

Poaching and various violations of hunting and fishing regulations and violations of harvesting quotas for animals are two other areas where most of the offenses are rural located. In these particular cases, the offenders can be thought of as mostly individual violators – such as hunters and individuals who make a living by harvesting fresh and seawater fishes – but both corporations and governments can also play roles in poaching.

As well, violations of environmental regulations for the use of chemicals by farmers, illegal dumping by individuals and corporations, and land-grabbing/theft, especially from indigenous peoples in countries like Brazil (White, 2012), adds to the list of serious environmental crimes which are also rural located. Finally, environmental justice issues have a significant rural dimension. The location of landfills in rural areas (or near working class/underclass neighborhoods in cities), the externality costs of fracking, oil drilling, and other forms of natural resource development, and impacts on crime and fear of crime from the boom and bust cycles created by energy development near rural communities, and many more – all point to significant problems associated with rural places whose long-term residents often lack the political capital to withstand environmental victimization and harm.

It could be argued that since a great deal of environmental crime is committed by individuals who are not permanent residents and that much of it represents complex crime networks that are regional and worldwide in scope, it is not actually rural crime. The counterargument is to apply the same logic in the other direction by pointing out that a crime committed in downtown Chicago by a tourist or visitor who lives at a rural place is in fact an example of rural, not urban, crime. A positive answer to the latter is nonsensical, as is the assertion made in the former. Hence, the ultimate solution is simple: first, ask where the crime or offense occurred; and secondly, then consider both the micro- and marcocultural, economic, and sociological factors associated with the crime at its place of commission.

Drugs

Drug use, production and trafficking in the rural context are perhaps the most thoroughly researched subjects of any in rural criminology. However, much of the research is not conducted by criminologists, but by scholars in the fields of public health, psychology, social psychology, and sociology. Nonetheless, along with the criminologists who pay attention to issues of drugs in the rural context, there is substantial evidence for the argument that it is at least as great a problem affecting rural peoples and communities as the urban populations of many countries. Consider, for example, evidence from the *Monitoring the Future* (MTF) research (Johnston et al., 2014). This annual study among a nationally representative sample of adolescents and young adults in the USA shows that today, there is little difference in rates of usage between respondents living in urban counties when compared to youth from rural counties for most illicit substances. Since the MTF has been continuously collecting this data, beginning in the late 1970s, it is also possible to trace when this convergence occurred, which indicates sometime during the 1990s. The results suggest that whatever immunities rural communities had at one time, which may be

based more on popular and criminological mythologies about the rural, those times are now lost (Donnermeyer, 2012).

A report by the Carsey Institute (Van Gundy, 2006) suggests how time and change affect the criminology of places, large and small. The report describes how mining companies in places like Harlan County, Kentucky dispensed painkillers as a way to squeeze more profit out of the labor of miners who had to crouch in the shafts of mines for long hours to extract the coal. Soon many of the locals were learning how to remove the time release coating on the pills to achieve a more immediate effect. With the emergence of a culture of drug use, the spread of newer and more powerfully addictive drugs like oxycontin and heroin was made easier. Similarly, Stallwitz and Shewan (2004) document the relationship of energy resource development as a source of social change and drug use. Specifically, in the Shetland Islands of the UK, the arrival of shipyard workers associated with port facilities constructed for the transport of oil from the North Sea brought with them the drug of heroin. However, it did not cause a moral outcry or panic, as the local culture, which was already attuned to pubs and heavy alcohol use, was tolerant of the new addiction with the rationalizations that the users were gainfully employed and did not engage in other crimes, such as burglary and unacceptable forms of public disorder. Hence, like the research by Barclay (2003), there are clear links between local forms of collective efficacy and crime.

Weisheit's work on both marijuana (1992) and methamphetamine (2008) production portrays the extent to which the supply of illicit drugs has a decided rural dimension, as does the previously cited work of McSweeney et al. (2014). Many rural places in the USA can be described as 'persistent poverty' counties, meaning that they have experienced above average levels of poverty for not only many continuous years, but for several decades (Economic Research Service, 2011). It is at these rural localities where drug use and drug production often can be found together. Garriott (2011) presents an intimate portrayal of methamphetamine's impact on the cultural and social life in a rural region of West Virginia. However, he does not demonstrate a relationship of social disorganization and crime, but instead how the social organization of a rural place was changed and reorganized by its introduction, including the ways local police operate, the emergence of drug clinics, and other coping mechanisms among its citizens.

Violence

There are two major strands of rural-located criminological science related to the subject of violence. The first is the work of criminological scholars who focus on violence against women, and in particular, violence by intimate partners. For example, DeKeseredy and Schwartz (2009) studied a rural region within the hilly or so-called 'Appalachian' area of southeastern Ohio. Although it is impossible to estimate the true rate of intimate partner violence, their research and previous work by other scholars (Donnermeyer and DeKeseredy, 2014) suggests that domestic violence may be much higher in poor, rural communities of the Appalachian region than in the city. More importantly, what they discovered is the extent to which forms of patriarchy pervade the social fabric of these communities. Based on their interviews, they found a 'male peer support system' important for enabling this form of violence. The support system consisted not only of learned rationalizations by men for why it is okay to physically and verbally abuse their girlfriends and wives, but of cohesive networks of peers who shared this information on a face-to-face basis. Abusers would meet at a local restaurant or other spots, sharing coffee, beer, rationalizations, and techniques to abuse without being detected by others. As well, violence against women was tolerated, that is, part of the normative culture of many of these small communities, and local law enforcement was sometimes reluctant to recognize domestic violence as an offense worth responding to.

What is perhaps most significant about their research is the spotlight they shine on the diversity of smaller places. This diversity is not in the traditional way criminologists think about it – which is racial, ethnic, or some other form of demographic variety in a population – but instead, is a form of sociological diversity. The research by DeKeseredy and Schwartz (1996) of violence against women at places with smaller populations helps to illustrate the geographic simultaneity of social organization which both enables and constrains crime. In essence, they and others who have focused on this subject in the rural context have found forms of collective efficacy associated with violence existing alongside forms of collective efficacy that constrain violence and other types of crime. Hence, violence against women is frequent, but robbery is infrequent. Similarly, research on violence against women in a number of other localities, from Australia to India to various African countries, demonstrates the relationship of social organization and culture to crime at specific places with smaller populations (Donnermeyer and DeKeseredy, 2014).

Another strand of research on violence in the rural context comes from those who look more generally at interpersonal violence, or more specifically at homicide (Donnermeyer and DeKeseredy, 2014). Some work on the culture of violence has examined possible statistical links of regional expressions of cultural themes, such as a 'culture of honor' in the southern USA (Nisbett and Cohen, 1996) to rates of assault and homicide. Others have taken a more qualitative approach and looked at how 'pub'lic (i.e., pubs as public places) expressions of masculinity are associated with interpersonal violence in many rural communities (Campbell, 2000). Still others have attempted large-scale statistical examinations of rural places and rates of homicide using the logic of social disorganization theory or related theories, such as civic community theory (a summary and test of both theories can be found in Wells and Weisheit, 2012), the results of which are discussed in the next section.

Rural Community Characteristics and Crime

Nowhere is the need for criminology to overhaul its theoretical focus more apparent than in studies of rural communities and crime. Further, nowhere has the burgeoning field of rural criminology presented a critique of mainstream criminological theory than the accumulated work on rural communities and crime. This body of research uses a very standard approach insofar as the research is: (1) regional or national in scope with a large number of cases; (2) the unit of analysis or case is a county or something else reflecting governmental jurisdictions

and boundaries; (3) the use of official police statistics for calculation of crime or arrest rates, combined with census or other secondary source data for measuring community characteristics; and (4) the employment of the logic of social disorganization theory and concepts like collective efficacy, social capital, and civic community (Donnermeyer and DeKeseredy, 2014).

This rural-based literature, mostly from studies conducted in the USA, consistently finds that economic indicators are not as strong in predicting variations in crime within rural communities when compared to urban-based studies. Specifically, the research has discovered that high poverty rural communities had lower official rates of crime. Further, these communities had relatively lower rates of population turnover or instability. Both findings are contradictory with the urban-based research, which claims that poverty and population turnover are forms of disorganization and conditions that weaken collective efficacy, hence, crime rates should be higher.

Since the research on rural violence, as noted above, seems to suggest the opposite finding for rural communities, the issue boils down to one of two explanations. One is methodological – the quantitative studies versus the more qualitative approaches of rural work on violence against women produces differing results because of the ways the data was collected and analyzed (police data versus personal interviews with victims). The other is theoretical, that is, theories like social disorganization are not generalizable to places with smaller and less dense populations without significant modification. Wells and Weisheit (2012) helped solve the dilemma by testing both social disorganization and a related theory known as civic community (Lee and Thomas, 2010) on arrest rate variations. As the population size of the county declined, so too did the predictive ability of both theories. As well, Kaylen and Pridemore (2012) addressed a series of inconsistencies in the rural findings that adopt a social disorganization perspective, and concluded that even though the mediating factors (i.e., cultural and social dimensions – the collective efficacy which is internal to a place) may be the same across rural and urban localities, the relationship of antecedents like poverty and population turnover (in the sense of antecedents in a regression analysis) to crime may be different between rural and urban communities. Hence, the problem has more to do with the theory of social disorganization and its reliance on the establishment of dependent variables derived from official police statistics.

In the past, some researchers (Donnermeyer, 2012; Weisheit et al., 2006) have noticed that there are indeed rural communities who manifest higher rates of official crime and arrests, such as recorded in the FBI's *Uniform Crime Reports*, than metropolitan communities. Hence, there is overlap in rates, which belie dichotomous thinking about rural and urban crime. Together, both the quantitative research on crime and rural communities (Wells and Weisheit, 2012; Kaylen and Pridemore, 2012) and scholarship associated with farm victimization by Barclay (2003), drug use by Stallwitz (2014) and Garriott (2011) and violence against women by DeKeseredy and Schwartz (1996) challenge directly the validity of social disorganization theory. This is important for understanding crime in the rural context because the deconstruction of urban-biased approaches to explaining crime and place are necessary before a full appreciation of the importance of crime in the rural context can occur. If sometime in the past, dichotomous thinking about rural = gemeinschaft = cohesion = less crime versus urban = gesellschaft = disorganization = more crime, had not yet been firmly set in place, and the comparative study of crime in places of different population sizes and densities had been more frequent throughout criminology's development, this challenge would not be necessary. Unfortunately, the growth of rural criminology was stunted by a past urban-centric approach to crime, and now that it has emerged as a vital field of inquiry, it is finding that place-based criminological theory needs revising, if not complete rewriting.

In Conclusion: Rural Mythologies

Rural crime should be taken seriously because it affects a significant share of the world's population. Even in countries with large criminological communities – Australia, Canada, the UK, and the USA – a significant share of citizens live and work at smaller, more rural places. This encyclopedia article has reviewed five primary areas where crime has a significant rural dimension, namely, agricultural crime, environmental crime, drugs, violence, and variances in crime and arrest rates across a diversity of rural community characteristics. There are other areas not reviewed here where the rural dimension needs more consideration, such as hate crime and significant presence of hate groups in rural places; crime at rural-located parks, recreation areas, tourist sites, and other places used by the general public; gangs and other forms of organized crime; arson; and issues associated with policing, courts, jails, and other infrastructural aspects of the criminal justice system.

Without a doubt, however, the emergence of rural criminology has already helped dispel two fundamental mythologies. The first concerns the weakness of a rural–urban dichotomy as an analytic shortcut to theorizing about crime. Rural places are incredibly diverse in their social, normative, and economic structures. It follows that expressions of crime vary across these places as well. In the earlier days of criminology's development, especially as an empirically-based science with testable theories, criminologists tended to relegate rural to a type of homogeneous residual or counterpoint to investigations of urban crime (Weisheit et al., 2006). Hence, theories such as social disorganization and concepts such as collective efficacy have one-sided interpretations. We now know that some forms of collective efficacy enable crime, while other forms constrain crime, and we know this from the work on rural crime. However, this truism applies to both rural and urban places, but in specific reference to rural crime, it demonstrates how a diversity of social structures exist, simultaneously, even in places that lack the outward complexity of cities. Whether the reference is to rural or urban places, there is really no such thing as social disorganization, only forms of organization which covary with expressions of specific crimes, which themselves may not always be positively correlated or covary in the same direction.

Second, places are rural (or urban) by virtue of their population size and population density. Nothing more! Within these smaller places is a greater heterogeneity of social organization, influence by normative orders and economic conditions,

and continuously changing, as do larger places. Hence, how they change overtime affects all aspects of crime, from crimes known to the police and those less likely reported by citizens to law enforcement, and to citizens' perceptions of what is a crime, what is safety, and what is the appropriate response. A rise in crime at a rural place cannot be merely interpreted as a feature of its urbanization, as this presents not a place-based or static dichotomy which has little value, but an equally useless time-based dichotomy with presumptions that the yesteryear of any place or of any society was relatively crime-free, and that it is only with industrialization and other aspects of modernization that crime arose. We know from history that rural places were never crime-free. Instead, the changing context of rural crime is a matter of examining the changing characteristics of smaller places (Liepins, 2000), just as the changing characteristics of urban places provides the context for understanding crime's ever-changing expression in the city.

Crime: Knowledge about and Prevalence

Rosemary Gartner, University of Toronto, Toronto, ON, Canada

Abstract

Crime is a core concept and concern in many societies, although what constitutes crime can vary substantially across time and place. This is because definitions of crime are the outcome of political processes and power relations that differ among societies as they struggle to achieve social order. Most of our systematic knowledge about crime and its prevalence relies on legal definitions that, like common-sense definitions, are socially constructed. After describing sources of information on crime, this article summarizes what is known about its prevalence and distribution over time, across and within societies. It concludes with an overview of explanations for historical and contemporary trends and patterns in crime.

Defining Crime

People in all societies, in the course of their everyday lives, interact and form relationships – with each other, with larger groups and organizations, and with social institutions, including the state – that can be marked by conflict, hostility, and exploitation. At times, the behaviors or situations that arise from these are termed 'crimes' or 'criminal.' In popular discourse, crimes are acts or events that violate fundamental moral precepts and deserve to be publicly denounced and punished. This common-sense definition implies that certain behaviors are inherently criminal and necessarily invite sanctions. However, because moral precepts – as well as responses to their violation – vary substantially across time, place, and people, common-sense definitions of crime cannot denote a fixed and natural category of behaviors.

In legal discourse, crime is behavior that leads to particular legal procedures and for which the law permits the imposition of criminal penalties. Here crime is constituted by legal definitions and reactions, not by characteristics inherent in behaviors. Legal definitions of crime appear both more precise and more objective than common-sense definitions: crime is what the law defines and treats as such. However, because legal systems are products of particular historical epochs, and legal definitions are created and applied through social and political processes, crime in this definition is both historically and socially constructed and contingent. What was once criminal (e.g., possession of small amounts of marijuana or certain sexual activities between consenting adults) is now legal, and what once was legal (e.g., dumping toxic chemicals into rivers or marital rape) is now criminalized – at least in some jurisdictions. As a consequence of the slippage between common-sense and legal definitions of crime, in every society many acts or conditions that are seen as harmful or morally repugnant (at least by some) are not legally defined as crimes; and some acts that are legally defined as crimes are not uniformly seen as harmful or immoral.

Since the late twentieth century, as social interaction and networks became more diverse and extensive and as new social movements gained force, new crimes and new categories of existing crimes have been created (e.g., cyber crimes, hate crimes, and transnational crimes). In addition, institutions that legislate and sanction these crimes have also emerged and grown – some of them, such as the International Criminal Court, in recognition of the increasingly global character of crime. These trends will continue to affect legal and common-sense definitions of crime, as well as debates over them, for decades to come.

Many social and behavioral scientists who study crime rely on legal definitions and restrict their attention to acts defined as violations of the criminal law. They differ, however, on the questions they ask about crime. Some are primarily interested in the behaviors defined as crime and the people who engage in them, whereas others are interested in the processes through which particular behaviors and people are defined as criminal.

Determining how much crime occurs and explaining why people commit it have traditionally been one of the principal concerns of those who study crime. Because there is no common behavioral attribute that ties all crimes together, the task of explanation is quite complex. How, for example, can one theory account for behaviors as diverse as possession of heroin, stock fraud, vandalism, bribery of public officials, and spouse assault – each of which violates the criminal law of many countries?

The difficulty of explaining crime as behavior suggests why other researchers direct their attention to the social and political processes whereby acts and people are criminalized. Here, crime is both a product of, and a discourse used in, struggles over how social order is defined and achieved; its lack of any essential attribute highlights its ideological character. This approach downplays the near-universal criminalization of certain behaviors, such as murder, assault, theft, and arson, and would point out that the acts included in even the most serious crimes, such as murder, can vary across societies.

A third group of legal scholars, criminologists, and philosophers engage in debates over the fundamental meaning of crime and the consequences of either restricting its definition to legal categories or expanding it, for example, to include potential or future behaviors. Those who object to more restrictive definitions argue that a range of harms to humans or violations of human rights are excluded from many criminal codes and therefore escape the attention of both legal officials and criminologists (Hillyard et al., 2004). Those concerned about more expansive definitions point to, among other things, the increased use of and confidence in actuarial tools and risk profiling technology to identify who and what may become criminal (Zedner, 2007).

Notwithstanding the conceptual challenges of defining crime, the combination of two elements is ordinarily recognized as critical: human behavior and a state-sanctioned response to it. Crimes of greatest concern in most societies also involve a third element: the intention to harm or wrong another. The more serious of these crimes – what are called *mala in se* (acts wrong in themselves) – are the target of substantial measurement efforts designed to answer questions about their prevalence, distribution, and causes.

Measuring Crime

Efforts to measure crime usually are guided by legal definitions of the jurisdiction of interest and rely on statistics and other information generated by criminal justice and legal officials. Most nations compile annual reports on the number of crimes known to police and the number of persons arrested or otherwise proceeded against by the criminal justice system. For example, in the United States, the Federal Bureau of Investigation (FBI) has compiled and published the Uniform Crime Reports (UCR) annually since the 1930s, based on data from several thousand police agencies; more recently, it has provided detailed data on lethal criminal violence in its Supplemental Homicide Reports. Vital statistics agencies, such as the National Vital Statistics System in the United States, are another source of official data on homicide in many countries. The World Health Organization's data on homicide mortality frequently are used to make comparisons among nations on levels of lethal criminal violence. Other important sources of official crime data from different countries include the International Police Organization (Interpol), the United Nations Survey of Crime Trends and Operations of Criminal Justice Systems, and the European Sourcebook of Crime and Criminal Justice Statistics.

While official statistics on crime from these and other sources are a mainstay of criminological research, they present three principal difficulties in measuring crime and documenting its prevalence. First, while legal definitions and official statistics provide a reasonably reliable guide to what is designated as criminal behavior within a given society at one point in time, they may not accurately measure differences across societies in similar types of behavior. This is because (as noted before) legal definitions of even relatively serious crimes vary across societies.

The second difficulty is that, for a number of reasons, official statistics do not accurately measure levels of crime even within a single society. Characteristics of official agencies that collect information on crime, such as the police, inevitably influence how these acts are interpreted and recorded. Some acts that fit legal definitions of crime may only infrequently be subject to criminal enforcement, such as many white-collar, corporate, or political crimes. Because the public is the primary means by which officials learn about crime, popular views on crime and attitudes toward the agencies that deal with it also influence which acts are reported to legal officials. So, for example, well under half of all physical and sexual assaults are reported to police in most nations (van Dijk et al., 2007). Police and other legal officials also have considerable discretion in deciding which acts or people to proceed against and how to categorize these in official records. As a result, official statistics on crime reflect less than its true prevalence as well as decision makers' perspectives on how to classify what are often complex behaviors and situations.

Relatedly, legal definitions, public and official perceptions, and public willingness to report crime also change over time within a society. Consequently, documenting even short-term trends in the prevalence of crime is subject to error in ways that are difficult to correct. These problems are compounded when official record keeping systems alter their methods of data collection or their coverage of law enforcement agencies, both of which have affected the FBI's UCR.

Unofficial sources of crime data, such as surveys of the general population, avoid some of these problems and shed light on the 'dark figure of crime' – that is, crimes that do not come to the attention of legal officials. Self-report victimization and offending surveys, which ask people about their criminal victimization or offending over a specified period of time, yield higher estimates of the prevalence of crime than do official statistics. Victimization surveys also show that the likelihood that a crime will become known to criminal justice officials depends in part upon characteristics of the victim, the offender, and their relationship – and that the more serious the crime, the more likely it is to be reported to and recorded by officials.

Since crime victimization surveys were first fielded in the late 1960s, they have been adopted as one of the major methods of measuring crime within many countries and at the international level. The National Crime Victimization Survey (previously the National Crime Survey), which has been conducted annually in the United States since the early 1970s, is the largest and longest running national victimization survey. Other national surveys are carried out regularly in Great Britain (the British Crime Survey) and in Canada (the General Social Survey). Because national surveys conducted in different countries have used different methods and measures, the International Crime Victims Survey (ICVS) was launched in 1989 to gather data that could allow comparisons among different nations. It has since been conducted about every five years and has collected data in over 70 countries and 35 capital or major cities. Modeled after the ICVS, the European Survey on Crime and Safety was launched in 2005 to document the extent and nature of crime in 18 member countries of the European Union.

Self-report offending surveys are much less extensive, in part because of the variety of problems involved in asking people to reveal their own criminal behaviors. The most common populations sampled by self-report surveys are young people, particularly high school or college students. One of the largest and longest running such surveys in the United States is the Monitoring the Future Study, which has been conducted annually since 1975 among high school seniors and since 1991 among students in the 10th grade and higher. The International Self-Report Delinquency Study has been carried out twice (in 1988 and between 2005 and 2007) among 12–15 years olds, most recently in 30 European countries and North America.

Because they rely on the honesty, memory, and perceptions of respondents, self-report victimization and offending surveys have their own limitations and biases. For example, asking someone whether they have been the victim of spousal assault in the last year may elicit a very different answer than asking the

same person if her husband has slapped her in the last year. Furthermore, victimization and self-report surveys can tap only certain types of crimes, that is, crimes with identifiable victims who realize they have been victimized (in the case of victimization surveys) or crimes with identifiable offenders who recognize they have committed a crime and are willing to admit to it (in the case of self-report surveys). As a consequence, some types of crime cannot be measured with survey data.

For these reasons, researchers sometimes rely on indirect and unobtrusive measures to document the prevalence of crime. These have included hospital emergency room records (to measure violent crimes), insurance company records (to measure property crimes), and air or water pollution scans (to measure environmental crimes). Participant or covert observation has also yielded valuable evidence about the extent of illegal behavior by police, illicit substance use and sales, and illegal sex work, among other criminal acts.

All efforts to measure crime inevitably confront the problem of defining a crime. Someone – a victim, a police officer, an offender, a witness, or a researcher – must apply a legal definition to a complex set of circumstances and human relationships. The difficulties in measuring crime, then, are not simply technical or statistical, but conceptual – and unavoidable. Consequently, it is impossible to determine the total amount of crime in any jurisdiction at any time. One can, however, count and describe with some accuracy events that are crimes according to the law and that come to the attention of legal officials, as well as criminal events which people report to survey researchers. These estimates form the basis of knowledge about the prevalence and distribution of crime over time, place, and persons.

The Distribution of Crime

Is there more crime today than in the past? For reasons already outlined, this question has no simple answer. To the extent that contemporary criminal law defines a wider range of behaviors as criminal, there is likely to be more crime. However, if we focus on the types of behaviors that most societies have defined as criminal or deserving of punishment and control, we can draw some conclusions about the distribution of crime over time.

The most reliable historical evidence pertains to serious violent crimes – such as homicide, robbery, and serious assault – in Western Europe and North America. By drawing on coroners' and court records, historians have documented levels of serious violence in a range of European jurisdictions at various time points over the last few hundred years. Piecing these records together shows that homicide rates were exceptionally high in the thirteenth and fourteenth centuries and then declined through the end of the seventeenth century (Eisner, 2003). After this point the downward trend became more gradual, although it was punctuated by short-term waves after wars and other major social dislocations. By the mid-twentieth century, most Western European nations were experiencing some of the lowest levels of serious criminal violence in their histories.

In the United States, after reaching relatively high rates in the first half of the seventeenth century, rates of homicide declined and – unlike today – were comparable to rates in Europe up until the early nineteenth century. At that point, lethal criminal violence in the United States took an upturn due to social and economic problems associated with immigration and urbanization and to the growing availability of hand guns. However, by the late nineteenth century in the United States, rates of homicide and other serious violence stabilized and in the late 1920s began a decline that lasted until the mid-1960s (Roth, 2009).

The centuries-long decline in criminal violence in Europe and North America reversed somewhat in the last third of the twentieth century. By this point, relatively reliable and comparable data on a range of violent crimes became available for many countries, allowing conclusions about trends in nonlethal as well as lethal violence. Beginning in the late 1960s, violent crime rates rose and then plateaued in most Western nations, whereas in many Eastern European nations, these rates increased dramatically beginning in the late 1980s and continued their upward spiral with the breakup of the Soviet Union. Trends in violent crime in the United States were similar to those in some Western European nations, with peaks in the early 1980s and again in the early 1990s.

Since the mid-1990s, however, both official statistics and data from victimization surveys show a steady, and in some cases dramatic, decline in violent crime in the United States and other Western developed nations. In some cities in the United States, the reduction in serious violence was remarkable. For example, in New York City there were over 2200 homicides known to police in 1990; in 2010 the number of homicides had dropped to just over 530. Similar declines occurred in aggravated assault and robbery and, to somewhat lesser extent, rape in New York City and many other places in the United States.

This 'crime drop,' as it has been termed by criminologists, has characterized a number of other countries as well. For example, official statistics and victimization survey data in Canada, England and Wales, and all of the Scandinavian countries show similar reductions since the early or mid-1990s. Similar to the pattern in the United States, in 2010 Canada's homicide rate reached its lowest level in 44 years, and the number of victims (554) was 25% smaller than the number of victims in the peak year of 1991.

It seems unlikely that the centuries-long decline in violent crime has been accompanied by a similar drop in property crime, simply because the growth in consumer goods and individual wealth means opportunities for property crime have increased greatly over the last few hundred years. However, reliable historical data on property crime do not exist. Before the advent of victimization surveys, even tracking more recent trends in property crime with any reliability was difficult because of the limitations of official statistics discussed previously. Since the late 1970s, however, both victimization survey data and official statistics show a drop in property crime (i.e., burglary, larceny, and motor vehicle theft) in the United States, paralleling the drop in violent crime. With the development of the ICVS, it has also been possible to estimate trends in property crimes in the developed countries where the survey has been carried out multiple times. These data show a substantial downturn since the mid-1990s in a range of property crimes, particularly burglary and motor

vehicle thefts, a finding paralleled by statistics from other sources (Harrendorf et al., 2010).

Are some societies more crime prone than others? Cautious comparisons can be made of direct contact, predatory crimes of individuals using victimization surveys and the data on homicides discussed earlier. According to these, rates of serious violent crime vary greatly, even across relatively similar societies, although these differences have diminished somewhat with the recent crime drop. For example, in 2009 Finland's homicide rate (2.3 per 100 000 population) was almost four times greater than Norway's (0.6), Belgium's rate (1.7) was more than three times greater than Austria's (0.5), the Russian Federation's rate (11.8) was more than twice as large as the Ukraine's (4.8), and the rate in the United States (5.0) was almost three times greater than Canada's (1.8) (UNODC, 2011). Among advanced capitalist nations, homicide rates are higher in the United States, Canada, and Australia. These rates are exceeded by those in Latin and South America and in Africa, where homicide rates are about twice as high as the global average. In contrast, homicide rates in Asia and Europe are about half the global average. The distribution of other serious violent crimes tends to follow a similar pattern.

Homicides and other serious violent crimes make up only a small part of the total crime rate, however. In all nations, most crimes are crimes against property. Traditionally, burglary and larceny (or theft) have been the major property crimes; of the 30 countries participating in the most recent wave of the ICVS (which does not include the United States), England and Wales had one of the highest rates of property crime victimization and Japan had among the lowest. Since the turn of the twenty-first century, consumer frauds of various sorts have become more widespread in many countries and may overtake more traditional property crimes, in large part because of the growth of the Internet, increased use of credit and debit cards, and other changes in banking and purchasing practices.

Although there is only limited research and almost no systematic data on national differences in white-collar, corporate, and political crimes – for example, theft by corporations, environmental destruction, or illicit violence by state agencies – these appear to be more common in developing countries. In part, this results from limited resources for enforcement and the ability of offenders to avoid prosecution. For similar reasons, activities of criminal organizations, such as trafficking in drugs, people and weapons, money laundering, and cross-border terrorism, may also be more prevalent in countries with emerging or transitional economies.

As this suggests, the economic and political organization of a country produces particular patterns of crime. For example, although the pre-1990s socialist countries of Eastern Europe had low rates of violent and predatory street crimes, other behaviors – worker sabotage, theft of nationalized property, bribery, and black market activity – were relatively widespread; and violent crime rates are higher in nations with greater inequalities in income and wealth and with fewer restrictions on the ownership of firearms.

Many of the social processes, conditions, or policies commonly thought to affect crime rates often do not do so, or affect only some types of crime. Urbanization and unemployment, for example, are not consistently accompanied by higher rates of violent crime, although they are associated with higher rates of property crime. Conversely, some social policies intended to decrease crime do not. For example, there is little evidence that the death penalty deters homicides or that high imprisonment rates are a cost-effective way to reduce crime. During the twenty-first century, the social process likely to have the greatest impact on the prevalence and distribution of crime – from street crimes to crimes of transnational corporations – is globalization (Natarajan, 2011). While there is nothing new about crime crossing national borders, unique opportunities for truly global crime have emerged with the rise of global capitalism, the expansion of electronic information networks, and widespread immigration and travel between countries and continents.

Just as certain national or global conditions or processes create opportunities and motivations for crime, so do more localized environments within countries. At the level of cities and neighborhoods, the prevalence and distribution of crime are not random. However, national context and culture affect the relationships between community characteristics and crime in complex ways, and so some of the relationships observed in the United States hold in other countries whereas others do not. Within the United States, for example, larger urban areas tend to have higher rates of violent and property crimes, but this association does not exist in all countries, even Western democracies; some of the least urbanized areas in Canada have among the highest homicide rates in the country.

Nevertheless, decades of criminological research have identified a set of characteristics consistently associated with high rates of serious, direct-contact predatory crime within the United States (i.e., at the state, urban, and neighborhood levels) and many other Western countries, including economic deprivation (e.g., absolute and relative deprivation), family disruption (e.g., divorce rates, single-parent families), and the geographic isolation of marginalized racial minority groups (Sampson, 2011). Some features of urban areas often assumed to be 'criminogenic' – such as population density, unemployment, or residential mobility – are related to some types of crimes but not others. Other characteristics are linked to crime, but in the direction opposite of what many people believe. For example, immigration is associated with lower levels of crime in many urban areas of the United States.

Neighborhoods and other local communities do not exist in vacuums. Consequently, the political, economic, and social processes and policies that allow local criminogenic conditions to develop and persist are generated by governments and major economic actors, which are in turn affected by national and global factors. Understanding the prevalence and distribution of crime at the local level therefore requires attention to multiple levels of analysis and processes that are at times quite distant from specific communities, even if their consequences are not.

Just as some communities are characterized by what are termed criminogenic structures and cultures, so are some organizations, both public and private (Friedrichs, 2010). Corporate crimes, state crimes, and other organizational crimes are also patterned by internal organizational characteristics (such as normative culture, lines of communication and authority, salary and other incentive structures) and external environmental characteristics (such as characteristics of competitors and regulatory agencies). The complexity of many

organizations and economic sectors – such as the financial sector – can also increase opportunities for criminal activity as well as decrease the ability of regulatory organizations to detect it. As a result, corporate and other organizational crimes proliferate and are more costly than all other types of crime combined. For example, the global financial crisis that began in 2008, which was prompted in part by fraudulent accounting and lending practices by major United States banks and financial firms, is estimated to have cost US taxpayers almost one-hundred billion dollars in 2009 alone.

State crime – that is, acts by state agents in the course of their duties that violate national or international criminal laws – can also be extremely costly, both financially and in human lives. Weak states run by autocrats can permit certain groups to expropriate public and private citizen's wealth and other resources for personal gain. At their worst, state crimes – from the torture of political prisoners to genocide – violate fundamental human rights in vastly more serious ways than any other type of crime. In recognition of this, in 2002 the International Criminal Court was established to prosecute individuals for genocide, crimes against humanity, war crimes, and the crime of aggression. By mid-2012 more than 120 countries were parties to the Statute of the Court.

Research on the prevalence of crime often focuses on the individual level and the characteristics of those who engage in criminal behavior and asks if some people are more likely to engage in crime than others. Once again, the heterogeneity of the acts comprising crime demands a cautious answer. Serious, direct-contact predatory crimes are the domain of young, economically disadvantaged males in virtually all nations. White-collar, corporate, and political crimes are also male dominated, though these are, for obvious reasons, rarely the preserve of the young and the poor. It is largely for victimless crimes – such as prostitution or drug use – and some low-level property crimes – such as minor thefts and frauds – that women's involvement at times rises to the level of men's.

Although some criminologists argue that there are few individual characteristics that consistently distinguish between people who engage in crime and people who do not, others disagree. The latter have highlighted psychological traits or characteristics – such as low self-control, impulsivity, psychopathy, or certain neurocognitive deficits – that are associated with many types of violent and other criminal behaviors. An important limitation of this research is that it focuses on a range of behaviors and actors that are unlikely to be representative of the entire population of crimes and offenders.

Explaining the Distribution of Crime

The decline in serious violence in Western Europe from the thirteenth century (and somewhat later in North America) up until the mid-twentieth century has been attributed to a number of different factors (Eisner, 2003). Certainly, the reduction in deaths due to homicide is at least partly the result of advances in medical technology, such that assaults are less lethal now than in the past. However, this cannot explain an apparently substantial decrease in nonlethal violence, which typically is ascribed to a set of broad cultural and social processes. Increases in self-control – which are captured by the concept of the 'civilizing process' (Elias, 1978) – as well as in informal and formal social controls, are central to explanations that focus on fundamental cultural changes.

While explanations that focus on large-scale cultural change can account for the centuries-long decline in violence, explanations of shorter-term deviations from that decline tend to focus on more structural factors specific to certain times and places. The widespread increases in both violent and nonviolent crime that began in the 1960s have yet to be fully explained, but are due at least in part to demographic changes (i.e., a growth in the population aged 15–29, the peak years for crime), shifts in routine daily activities away from the home, high rates of marital disruption, and growing economic inequality. In the United States, the emergence and expansion of crack cocaine sales and use also helped drive crime rates up in the late 1980s and early 1990s.

What is less clear is why both violent and nonviolent crime rates dropped not just in the United States but in a number of other Western developed countries, beginning in the mid-1990s. Many explanations have focused on factors specific to the United States (such as rising imprisonment rates, changes in policing practices, declines in crack cocaine use, etc.), but these cannot account for the crime drop in other countries that did not experience these changes. Perhaps there was a reemergence of the broader cultural shifts responsible for the long-term decline in crime, combined with a set of other, more country-specific factors (such as a reduction in childhood exposure to lead). Criminologists continue to explore a number of possibilities but as yet have reached no consensus about the driving forces behind the downward trend that continued throughout the first decade of the twenty-first century (Baumer, 2011).

Most explanations for variations in crime rates among and within countries or between individuals feature one of three mechanisms: motivations, controls, or opportunities. Motivational explanations focus on social conditions or processes that generate criminal tendencies in societies, groups, or individuals. Criminal motivations have their roots both in social structure – institutional patterns and processes that organize interactions and relationships – and in culture – accumulated traditions and shared experiences that shape the values of a society or group. Economic inequality is a structural characteristic strongly associated with high crime rates and is thought to increase motivations for crime by fostering alienation and hopelessness. Norms that advocate criminal acts under certain conditions are a cultural factor that may motivate criminal behavior.

Control explanations focus on social conditions and processes that weaken internal and external, informal and formal controls on crime. Both structural and cultural factors can affect social control. Crime tends to be lower in societies with stable families and integrated community networks because these strengthen controls on criminal behavior. Crime tends to be higher where group norms excuse or tolerate crimes against certain victims (e.g., against spouses, organizations, sexual minorities, etc.) because these cultural features weaken controls.

While motivational and control perspectives are primarily concerned with potential offenders, opportunity explanations

focus on the circumstances in which crimes occur. Situations in which a motivated offender encounters a suitable target in the absence of capable guardians create opportunities for crime (Cohen and Felson, 1979). Patterns of routine daily activity that take people away from home foster opportunities for burglary, mugging, and auto theft. Criminal opportunities are also greater where small consumer items are mass produced.

Some general theories of the prevalence or distribution of crime have been widely tested and command substantial support. At the same time, there is considerable debate over whether a general explanation of crime is possible or even desirable, given the heterogeneity of crime. Nevertheless, some generalizations about the sociocultural contexts that appear to discourage direct contact, predatory crimes can be drawn. These are characterized by (1) strong systems of informal social control reinforced by highly consensual normative systems; (2) strong networks of communal obligation and mutual interdependence; and (3) cultural orientations that discourage cynicism about mainstream social institutions. Societies with these characteristics tend to be organized around collectivist rather than individualistic principles. These principles in turn are reflected in political, economic, and legal ideologies and practices and generate similar characteristics at the local or community level. These generalizations are grounded in research on a limited range of criminal behaviors, however. Too little is known to develop similar generalizations about many types of crime, such as those by transnational corporations and national governments, although this is changing. Until these types of crime can be more systematically documented, understanding of the prevalence and distribution of crime will be incomplete.

Abstract

The problem of organized crime has captured the attention of scholarly research, federal legislation, popular culture, and the imagination of the public for decades. The definition, conceptualization, activities, and overall analysis of organized crime have also undergone important developments in sociology, political science, economics, law, and other interdisciplinary fields. This article offers an overview of this body of research with descriptions of the current understandings of (1) what constitutes organized crime/organized criminal groups and their activities and (2) different avenues of analysis and approaches to research on organized crime.

Introduction

Definition

The idea of organized crime generally refers to crime that is organized (i.e., committed by groups of more than two persons) as well as to various other typologies and forms of criminal groups such as street gangs or youth gangs (Varese, 2001). That is, organized crime refers to both types of activities as well as types of groups. Organized crime groups are typically characterized by

1. a formalized structure with some sort of governance system that is maintained by some combination of force, the use of violence, and appeals to personal and kinship ties;
2. monopolization of the production and distribution of some commodity, usually illegal goods and/or services;
3. resilience in time, with development, expansion, or reorganization, sometimes into legitimate (noncriminal) sectors of politics and/or the economy; and
4. a sense of collective identification as a group, society, or organizational entity (Gambetta, 1993; Schelling, 1984; Lupsha, 1995; Ayling, 2011).

The most commonly portrayed (and studied) organized crime groups are often generally termed 'mafia,' a term originally applied to describe Italian criminal groups, but has since been challenged as a misnomer and applied cautiously (Varese, 2001). However controversial or inadequate, the mafia is distinguished from organized crime as a whole in its identity as a separate relatively autonomous entity, such as a particular crime group like the Russian *vory v zakone*, 'relatively autonomous' in its stance with respect to legitimate and illegitimate criminal organizations. Most of empirical research (not to mention, popular culture) considers the mafia to be the 'archetype' of the organized crime group. But in fact, we know very little about other types of organized crime groups. In this sense, while mafias are integral to the study of organized crime, further investigation is needed to better understand organized crime as a whole.

Types of Activities

Mafias and criminal groups defined as organized crime have historically been involved in criminal activities such as racketeering, money laundering, bootlegging, and drug trafficking. In recent decades, there has been increased concern about the involvement of organized crime groups in human smuggling and sex trafficking (Ayling, 2011) in addition to ongoing issues with drugs and arms trafficking. In general, organized crime groups engage in providing illicit goods and services, and are often able to infiltrate legitimate businesses and institutions.

Criminal activities such as drug trafficking are characterized as 'organized' primarily due to more sophisticated levels of logistics and delegation of tasks as opposed to, say, street crimes such as robberies that often involve little planning and organizational wherewithal. Drug trafficking at the level of organized crime is therefore distinguished in complexity from street corner drug sales by local gangs because it involves moving large quantities of narcotics often across state and international borders – a task that requires both organizational capacity as well as connections to noncriminal entities. The scale of such drug trafficking by organized crime groups requires more planning and organizational structure, similar to that of a legitimate corporation.

Roots of Organized Crime

Social Disorganization

The most common theories on the origins of organized crime rely on three main themes: social disorganization, existence of weak government, and functional theories. First, social disorganization refers generally the inability of a community to realize the common values and goals of its residents to maintain effective social controls (see Sampson, 2012: p. 37, for a review). Typically, social disorganization arises in communities with high population turnover, a lack of resources, and a greater level of population heterogeneity, and more broadly from consequences of industrialization, urbanization, modernization, and the growth of free-market capitalism in democracy, in parts of the world. The original Chicago School interpretation of social disorganization held that such shifts in communities diminished the functioning of social institutions such as families and community organizations that would otherwise monitor resident behavior (e.g., Shaw and McKay, 1942).

The consequences of social disorganization include increased poverty, social injustice, poor health conditions, and violence. In particular, conditions of social disorganization often stir the development of criminal subcultures and groups of all types as a means not simply to deal with harsh living conditions but also to fulfill needs otherwise left unmet (Steffensmeier and Martens, 2001). Much organized crime, particularly in the United States, arose from the impetus to seek financial prominence and elevated status in the wider community (not necessarily criminal). Indeed, sociologist Robert K. Merton uses none other than the notorious gangster Al Capone as a prime example of how organized crime can be an adaptation to structural conditions and an illegal means to the American Dream (see also Bell, 1953).

Weak Government

The second main theory of the origins of organized crime is the concept of weak government. Criminal organizations are more likely to emerge and develop where government is seen as corrupt, unstable, or insufficient/inadequate over territory under its control. Organized crime groups arise to ostensibly fill in this governance vacuum, sometimes addressing real needs for a certain type of stability, but more often than not exploiting this power gap to advance organizational goals or status. Organized crime in many countries, as in Sicily and during the Stalinist period in the former Soviet Union, has stemmed from rule by authoritarian or oppressive regimes. Such governments generate conditions that enable groups to form for self-protection and provision of quasi-governmental services (Steffensmeier and Martens, 2001).

Conditions such as these, in turn, give rise to a system of beliefs and attitudes toward society and government (distrust, clan mentality, inclination to use violence and vigilante tactics, corruption of law and influential figures in politics, exploitation and use of local – and in the case of ethnic criminal groups, members of the ethnic group – residents to manipulate influence), all of which is conducive to the formulation and growth of organized crime (Cressey, 1969; Pennsylvania Crime Commission, 1991; Steffensmeier, 1995; Steffensmeier and Martens, 2001). For instance, criminal syndicates in Russia after the Bolshevik Revolution (Varese, 2001; Solomon, 1996) and former Soviet Republics such as Ukraine in the 1990s (Serio, 2008; Humphrey, 2002) after the collapse of the Soviet Union arguably arose from instability, rising corruption, and a demand for access to basic goods (bread, alcohol, meat) which otherwise were in short supply or available only to the political elites. In cases such as these, and many others, organized crime groups exploit the opportunity to insert themselves within the social organization of a community.

Without a strong or functioning government, organized crime groups can posture themselves as *de facto* leaders/rulers, i.e., preside over kangaroo courts, mete out justice, and provide basic services, but at a cost.

Functional Theories

Organized crime is also thought to stem from a number of 'functional' reasons in the sense that its emergence serves a basic function or multiple functions – positive or negative – for some segment in society (Cressey, 1969). Such functions can include providing illicit incomes in communities lacking legitimate employment opportunities, entry into political and economic spheres for disenfranchised populations, and social and financial aid as a form of off-the-books welfare systems (Steffensmeier and Martens, 2001).

Several scholars contend that much of the illegal activity conducted by member of organized criminal groups is connected to, and often dependent on in a practically symbiotic sense, legitimate (legal) organizations, institutions, and actors (Steffensmeier, 1986; Steffensmeier and Martens, 2001; National Research Council, 1999). That is, organized criminal activities often exist precisely because they require connections with the legitimate world not only to market illicit services and goods but also to maintain connections to public officials who can help organized criminals avoid detection and apprehension. One of the defining characteristics of organized crime is its ability to forge such connections and interdependencies, interacting with and infiltrating mainstream social institutions through networks (see more in Section Organized Crime as Networks, also Papachristos and Smith, 2013).

In this sense, organized crime is not so much a separate or entirely autonomous group apart from mainstream society. Rather, organized crime is integrated into many social and political components that influence the effective control and functioning of greater society. These deep-seated issues are also evidenced by organized crime's role in certain economic sectors such as the prominent issue of labor racketeering into organized labor unions in mid-twentieth-century America saw crime groups like the Cosa Nostra exerting influence on a movement with major impact on the U.S. economy (Jacobs, 2006).

The 'Gray Economy'

One of the more studied activities of organized crime is its role and functioning in illegal markets and economics which often highlight the role of organized crime in a community as well as its relationship with legitimate social institutions. In terms of organized crime and quasi-legal activities in general, this is referred to as the 'gray economy' or the 'shadow market.' The gray or 'shadow' economy is typically defined as market economic activity that goes unreported to the government (e.g., Feige, 1989). Such economic activities are those that may not necessarily be illegal, but are 'under the radar' of typical economic oversight and measurement (i.e., GDP). The provision and exchange of goods and services by criminal groups can be considered to fall into this category of economic analysis, which reiterates the interconnectivity of organized crime and legitimate institutions and actors in society. For example, in the post-Soviet period in the 1990s, criminal groups in former Soviet states such as Ukraine and regions of eastern Russia regularly participated in an underground economy, providing everything from food products to illegal substances, effectively evading enforcement from governments that were themselves economically unstable and corrupt (Humphrey, 2002). Common organized crime gray market activities include tax evasion (Ayres, 1996), money laundering, arms smuggling (Nordstrom, 2000), and many other illegal to borderline illegal activities that have escaped government monitoring or legitimate authorization (see Bucklin, 1993).

Scope and Structure of Organized Crime

The scope and structure of organized crime is generally understood through four different conceptual paradigms: as ethnic subcultures, as hierarchies and bureaucracies, as patron–client structures, and as networks. These perspectives in understanding organized crime are a condensed summary of the relatively wide variation in the composition, structure, and development of criminal groups whose relations to mainstream society and broader organized crime syndicates are becoming increasingly complex due to resilience and varying degrees of institutional evolution (Ayling, 2011).

Organized Crime as Ethnic Subcultures

Organized crime can be understood in terms of different groups acting as ethnic subcultures or, at least, as being dominated by distinct ethnic subcultures within the larger society in which a particular organized crime group operates. For instance, the Mafia in the United States is often depicted and studied as a set of distinct ethnic groups, but especially Italian and Sicilian (Gambetta, 1993, and others). As mentioned above, activities of organized criminal groups have at times been connected with an ethnic group's need to survive and thrive in a foreign and changing environment. Particular ethnicities and cultural practices provide a repertoire of already existing traditions, values, rituals, and common understandings that can be adapted or manipulated in establishing and promoting activities of organized crime. Within the subgroup, especially a disenfranchised and marginalized subgroup, one would presumably encounter resistance or distrust of official authority and government, perceptions of inadequacy toward the law (i.e., 'legal cynicism'), in-group trust, and insularity, which are all conducive to the reinforcement and development of the overarching 'culture' of organized crime (Steffensmeier, 1995; Steffensmeier and Martens, 2001).

Organized Crime as (Ethnic) Hierarchies/Bureaucracies

The structure of organized crime groups is often conceptualized as hierarchical or bureaucratic systems, where decisions are made top–down, to the benefit of the organization and its survival. In scholarship/research on the Italian Mafia and the Russian Mafia, this nearly institutionalized structure can be seen, particularly when focusing on the criminal activities within the 'gray market' of the economy (see Gambetta, 1993; Varese, 2001). The main idea is that actors involved in organized crime and illicit goods and services follow a similar script of rational behavior indicated by mainstream/legal economic actors and institutions. To illustrate this point further, organized crime has been analyzed as an 'enterprise,' (see Steffensmeier and Martens, 2001) especially in activities such as racketeering.

In racketeering and other entrepreneurial activities, organized crime can be seen as a 'business' that deviates in its legality from commonly understood business activities but shares much of the ideology and ethos of legal businesses (Smith, 1980; Steffensmeier and Martens, 2001). In regarding organized crime as a business, however illegitimate, focus is directed again to the functions and benefits to the organization itself, and the necessary arrangements and relationships it has with legitimate businesses. Chinatown gangs are a prime example: they often rely on extortion of Chinese businesses in Chinatown for revenue and establishment of authority (Chin, 1996). Chinatown organized crime groups therefore infiltrate legitimate businesses, providing policing and loans, but at a high cost of exploitation. Bootlegging during Prohibition was so large and extensive that many operations ran with businesslike precision, orchestrating international production and distribution systems, operating local speakeasies, and literally paying hundreds of employees, including brewers, truck drivers, hired goons, crooked cops, and even politicians (Haller, 1990; Papachristos and Smith, 2013). In short, many organized criminal activities require the sort of organizational structure and business acumen often valued in legitimate business ventures (Merton, 1938).

Often organized criminal activities are so similar to those of legitimate businesses that distinguishing illegal groups becomes difficult at the expense of enforcement and legal prosecution. For instance, in China, such ambiguities in definition make it difficult for legal authorities to properly understand what they are up against, with most assuming that such groups are hierarchical, when in fact they are widely varied from market-based enterprises to personal network systems (Xia, 2006; Chin and Zhang, 2008).

Organized Crime as Patron–Client Structures

Similarly, organized crime can be structurally understood in terms of a patron–client relationship. Patron–client relationships operate in such a way as power and access to particular resources rests in the hands of a central figure (the patron) who manages access to resources and brokers relationships. Those seeking access to said resources (the clients) must negotiate with the patron, often indebting themselves or otherwise entering into a subordinate position in the network, offering loyalty and allegiance in exchange for the patron's attention and resources (see Steffensmeier and Martens, 2001). In such relationships, connections are invaluable for access to illegal activities (perhaps through legal or quasi-legal methods) (Albini, 1971; Ianni and Reuss-Ianni, 1972; see Steffensmeier and Martens, 2001). Key individuals in positions of power and prominence are approached for favors and other services such as protection, important connections, and resources (Albini, 1971; Steffensmeier and Martens, 2001). More recently, research is redirecting the focus from patron–client relationships, where ties are already complex to a focus on the interconnectivities of networks dictated not by a strict top–down hierarchy but rather by a symbiosis of social circles and exchange of influence (Papachristos and Smith, 2013).

Organized Crime as Networks

An emergent field in understanding organized crime is applying social network analysis to the study of organized crime (see Morselli, 2003). Understanding organized crime syndicates as networks allows research to expand and transcend traditional perspectives on the structure and activities of organized crime groups. In fact, the application of social networks

to organized criminal groups is arguably intuitive: such groups, varied as they are along social, ethnic, and historical lines, are characterized by network relationships within and without the group. The Cosa Nostra relies on connections, affiliations, and exchanges as much as Chinese criminal syndicates rely on 'guanxi,' the Eastern conceptual equivalent (McIllwain, 2000). Similarly, the transcendental nature of using social networks in analyzing organized crime groups highlights and bridges entrepreneurial elements and activities within the criminal group with noncriminal institutions and actors such as legitimate businesses and politicians. The New York Gambino crime family (among others) had intragroup and intergroup connections that enabled upward mobility from within the family ranks as well as development of the criminal enterprise to infiltrate legitimate businesses (Morselli, 2003). Another example is the reliance on personal networks of family, friends, and acquaintances that allow criminal actors to place themselves in strategic positions of influence and control over resources, licit and illicit, in order to both expand and strengthen a criminal group's hold over a certain region or community such as with Hong Kong Triads in U.S. Chinatowns and the Russian 'Mafia' in the U.S. (Chin, 1996; McIllwain, 2000; Morselli, 2003; Finckenauer and Waring, 1998).

Recent research has also focused on the dual concepts of 'embeddedness' and 'multiplexity' (Granovetter, 1985; Papachristos and Smith, 2013) within social network analysis and organized crime research. The placement of different social relationships in multiple types of networks is analytically combined to better illustrate and understand that the social circles in which individuals operate and are situated often not just involve multiple realms of politics and society but also interact and influence one another in a variety of possible ways (Papachristos and Smith, 2013). In short, emphasis on interdependencies of actors in criminal and noncriminal networks provides a helpful method to thinking about and researching organized crime that reaches beyond classical conceptualizations of structure and criminal activity in such groups.

Organized Crime in the United States

Much of organized crime research and theory has focused on organized crime in the United States, particularly mafias of various ethnic subgroups located in the country. In recent years, as organized crime has grown along with new advancements in technology and communication, more and more research is broadening to include previously overlooked groups in their apparently nascent stages and the issue of transnational organized crime. As previously stated, not only are such organizations expanding but their activities and practices are increasingly merging internally and externally with mainstream social, political, and economic activities (Steffensmeier, 1995; see Steffensmeier and Martens, 2001). Organized crime as treated in this article refers only to large-scale enterprises with highly organized structures and sophisticated distribution and application of resources for illegal activities. While biker gangs and drug cartels are part of the larger umbrella of organized crime, discussion of these criminal groups in the U.S. is outside the scope of our analysis.

Mafia in the United States

Organized crime in the U.S. has historically centered on the early immigrants to the country: Irish, Eastern Europeans, and Italians. The Italian-American Cosa Nostra has dominated the conception and study of organized crime in scholarship and popular media, but increasingly more research is focusing on Chinese and Hispanic involvement in organized crime, particularly as immigration (and controversial immigration policies) has increased as well.

In addition to the U.S. Mafia associated with the Cosa Nostra, there have also been studies on Chinatown gangs (from Hong Kong Triads and 'tongs'; see Chin, 1996) and Asian-American organized crime as a whole, mostly located in Los Angeles, San Francisco, and New York, where Asian populations (East Asian, Southeast Asian) are typically high. These criminal groups, along with broader examination of organized crime in other subgroups (bikers, Blacks, Colombians, Dominicans, Jamaicans, Mexicans, Syrians, Lebanese, and Russians) previously underresearched and seen as 'emergent' subgroups, are gaining prominence in the literature (see Finckenauer and Waring, 1998). These groups are typically involved in trafficking illicit goods, especially drugs, but in recent years, human smuggling and sex trafficking have also come to greater attention, particularly as these criminal activities have reached the global level.

Transnational Organized Crime and Organized Crime in Other Countries

China (Mainland, Hong Kong, and Taiwan)

While research in Asian organized crime as a whole has increased, most of it has focused exclusively on human smuggling and drug trafficking (Chin and Zhang, 2008). Aside from a few exceptions (Chin, 1996, 1999 and others), most studies of Chinese organized crime have also largely depended upon secondary sources, particularly analysis of media coverage and government reaction/response. Empirical research that has relied on more direct contact with victims and perpetrators of criminal activity has dispelled traditional assumptions that single sophisticated organized criminal groups – such as the Hong Kong Triads – were responsible for the majority of human smuggling (Chin and Kelly, 1997). Most smuggling operations are conducted by individuals known as 'snakeheads,' who are locally or often familiarly connected to the illegal immigrants (Chin and Zhang, 2008).

Other important headway made in Chinese organized crime research is focus on the often symbiotic relationship between the Chinese government and criminal organizations. The Chinese government itself has not officially recognized the problem/existence of underworld organizations originating and stretching from Mainland China to Taiwan to Hong Kong and Macao (Chin and Godson, 2006). The current political system and situation in China are impediments to deeper research and acknowledgment of real and widespread issues pertaining to such criminal groups. In the meantime, groups from the Mainland are finding it increasingly easy to gain legal protection and legitimacy for their illegal conduct from the government (Chin and Zhang, 2008).

Russia

Deriving its historical roots from criminal organizations in Stalinist prisons, the Russian Mafia grew from multiethnic roots to a transnational criminal network. The structure of the organization has arguably remained hierarchical, but is now more flexible (Varese, 2001). The Russian Mafia is not a single organization, but a combination of criminal leaders with historical origins in Soviet criminal groups (Varese, 2001). Because of the very historical and (anti) political origins of the Russian Mafia, there are legacies of the Mafia's foothold in the government and the economy. Despite the lack of unified identity in the proliferation of the Russian Mafia (with a composite of multiple subgroups of different ethnicities and spreading to countries now independent from the former Soviet Union), the Mafia itself has lasted for many years and has the advantage of an international network.

Italy

Most research on organized crime in Italy has centered on Sicily. In extant research, Sicilian organized crime is characterized as a formalized, structured group, relying on codes of communication that enable effective signaling within and outside those groups (Gambetta, 1993, 2009). Communication among criminals is necessary not just in order for a heist or crime to go smoothly, or even so much to promote mutual trust, but rather to be able to signal their own 'criminal credentials' (Gambetta, 2009). Intuitively, the more structured a group is, the more structured its signaling system. Similar to research on organized crime in China and Russia (and the former Soviet Republics), research on organized crime in Italy emphasizes complex in- and out-group interactions and ties with legitimate institutions, which appear to be the driving force behind the continuity of organized crime.

Other Countries

The extent of organized crime as a global, transnational problem is evidenced in its appearance in various forms in many different countries, spanning continents. In addition to the Chinese organized crime groups mentioned above, the Yakuza are the main organized criminal entity in Japan. The Yakuza have a long history and comparatively formal structure, with recognizable gang regalia (tattoos, hairstyles, and clothing) and participation in gambling, prostitution, and trafficking (Hill, 2003). Other criminal groups can be found in South America, namely Brazil; Central America and the Caribbean (Mexican drug cartels, gangs in Jamaica); and the Middle East (Israel) (Manwaring, 2007; Siegel, 2003).

Abstract

The goal of anti-crime public policy is usually understood to be the interception of and/or prevention of criminal acts. At first impression, this statement is simple and straightforward. However, even a cursory overview of crime policy in operation presents a much more complicated picture.

Briefly, four topical areas illustrate the difficulty of determining how government can best respond to crime (and there are surely others not specifically covered in this article). These four categories of issues in crime policy can be labeled 'sociological, legal, governmental, and practical.' This article will consider each topical area in turn, offering examples to illustrate major issues and problems.

The goal of anti-crime public policy is usually understood to be the interception of and/or prevention of criminal acts. At first impression, this statement is simple and straightforward. However, even a cursory overview of crime policy in operation presents a much more complicated picture.

Briefly, four topical areas illustrate the difficulty of determining how government can best respond to crime (and there are surely others not specifically covered in this article). These four categories of issues in crime policy can be labeled 'sociological, legal, governmental, and practical.' The sociological approach regards crime as a matter of social deviance from the norm, and it raises two fundamental issues: (1) what is the definition of crime? and (2) what causes people to commit crimes? The state defines the crime and also develops policies and programs based on what the legislative and executive branches' beliefs about 'why people commit crimes' may be. The legal approach proceeds from a positivist assumption that crime is what the legislature says it is, so laws and their interpretation are its focus. Its fundamental threshold issue is how can the law (most importantly, the nation's Constitution) be written and applied so as to reduce crime while simultaneously providing the fullest measure of personal and political liberty? The governmental approach has as its goal the enforcement of this law, and its primary concern is which agencies of government – and perhaps private parties acting in partnership with them – can be mobilized most efficiently and effectively to achieve that goal? Practitioners in the field are generally most concerned with the fourth topical area, the 'practical,' which concerns the structure and operations of governmental agencies of criminal justice. The fundamental underlying question for them is: what works to reduce crime, and how can the agencies of criminal justice be improved?

This article will consider each topical area in turn, offering examples to illustrate major issues and problems. These examples are not meant to comprise an exhaustive list. In fact, they constitute only a very small number of criminal justice policies that could be cited and explored. They are offered only as useful illustrations that are chosen because they have been recently discussed widely in popular media and scholarly research. Most of the examples are taken from US crime policies, but similar questions and programs are observable internationally.

Taking the four topical areas in order, hundreds of examples of crime policies under each could be cited, but this article covers only a few which can serve as illustrations. Examples of the sociological concern about 'what is crime?' are the varied policies about use of drugs, immigration, or white-collar deviance. (The second sociological concern, 'what causes people to commit crime?' is important because any particular crime suppression policy must be rooted in the expectation that it will affect a cause of crime; however, this concern is primarily criminological and thus is beyond the scope of consideration in this article.) An example illustrating the tension between security and liberty is legal policy about surveillance of electronic communications, Internet use, and merging of data about consumer choices into metadata made available to law enforcement for crime suppression. Also involved is the classic tension between due process and crime control. Examples of governmental structural concerns involve the proper role of the various agencies of the criminal justice system in crime reduction: police, prosecutors, courts, and agencies designed to punish criminals often overlap in their functions or take on characteristics of each other which may violate separation of powers necessary for checks and balances. Examples of practical policies are laws or programs which are expected to reduce crime – for instance: capital punishment, policing through aggressive surveillance and intervention in street encounters, gun control, diversion from prosecution of persons charged with drug or property crimes, granting immunity from prosecution in return for a defendant's cooperation in convicting others, operation of treatment or 'problem-solving' courts, reduction of bloated prison populations, and providing social support for ex-offenders upon reentry into public life after having served their sentences in prison. Any of these programs or policies – and there are many, many more – can be evaluated in cost–benefit terms, in terms of fidelity to the law, in terms of management efficiency, and/or by other methods.

Finally, note that all these public policies and governmental operations function at several different jurisdictional levels. Crime is generally regarded as primarily a matter for local government, considering that individual criminals live in local communities and that particular conditions and neighborhood knowledge are critical in responding to criminal acts. However, local law enforcement and jails must operate within the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86155-3

framework required by state or provincial law, and authority to operate prison systems usually is lodged in the law of the larger jurisdiction. Similarly, a province or state usually has its own police agency with statewide jurisdiction over crimes affecting the public in the many local jurisdictions (for instance, traffic enforcement on state highways, or consumer frauds committed by the same criminal enterprise in many different cities). Similarly, in the United States, a federal criminal justice system takes jurisdiction over crimes that occur in multiple states (for instance, drug smuggling, or frauds committed by corporations doing business in many states) or crimes against federal entities (e.g., corruption among elected federal officials) or crimes committed on federal lands (e.g., Indian reservations or the District of Columbia).

Similarly, international crime policy addresses matters of genocide, human smuggling, international terrorism, and other crimes. The international law principle of universal jurisdiction holds that a former head of state can be held to account by public trial for human rights violations – war crimes, crimes against humanity, genocide – which occurred during the official's term of office. A permanent International Criminal Court (ICC) has recently begun operations. Not only state officials but also persons acting in their individual capacities as war lords or torturers are also subject to the ICC jurisdiction (Schabas, 2011). The ICC handed down its first conviction against Thomas Lubanga of the Congo, for war crimes, in 2012. The United Nations can call upon the Court to begin proceedings – as, for example, against North Korea for committing crimes against humanity including rape, forced abortions, enslavement, and religious persecution 'meant to sustain the current political system' (United Nations, Human Rights Council, 2014). The power of this new Court is likely diminished by the refusal of several powerful counties, specifically the United States and China, to support it. One reason the United States might not be willing to support the International Criminal Court is that the Court may prosecute heads of state who are alleged to have engaged in torture for political ends, so ex-President George W. Bush might arguably have been subjected to prosecution for interrogation practices used against alleged terrorists incarcerated at Guantanamo Bay. Because this article covers crime policy in the United States, these international topics are not covered further here.

Policy Defines Crime

Universally, *mala in se* crimes (translated: 'evil in itself,' or 'intrinsically bad') are regarded as violations of the law in all nations. These roughly correspond to violent felony crimes: homicide, rape, robbery, and assault. In addition, theft is universally considered to be a crime, although the conditions under which the property is taken may or may not cause the action to fall under the category of crime.

Nevertheless, the assumption of universality is challenged when legislation and law enforcement policies are seen to vary across jurisdictions and time. The laws about whether a homicide is justifiable, for instance, vary among states within the United States. Recently, the 'Stand Your Ground' law was hotly debated in a Florida case that drew considerable public attention. 'Stand Your Ground' laws have been passed in approximately half of states in the United States. These laws state that a person who reasonably perceives him- or herself to be at risk of bodily harm, in any place where he or she is lawfully present, may defend using any force necessary. In these jurisdictions, a person is under no obligation to yield to threats even if the assailant can be avoided. If the local prosecutor would determine that a person perceived that an alleged attacker presented a serious threat of bodily harm, no murder has occurred if the former kills the latter – even if it would have been easy to avoid it.

In the Florida case, Trayvon Martin, an unarmed black teenager, was shot and killed by a white Hispanic neighbor, George Zimmerman, who said he believed that Martin was suspicious and that the teenager had threatened him when Zimmerman attempted to question him on the street. The prosecutor charged Zimmerman with murder, but only after public outcry at her initial refusal to do so. The prosecutor had to prove that Martin had not threatened Zimmerman; if he had, the 'Stand Your Ground' law would have applied and the threats would have constituted a defense to the killing. The jury found that Zimmerman reasonably believed he was being threatened and acquitted him. (This verified the prosecutor's original opinion, but public outrage had to be taken into account.) The case highlighted racial animosity in Florida and sparked protests about laws that seem to be aimed at racial minorities.

Evaluations of Stand Your Ground laws in practice are contentious. However, states do report to the Federal Bureau of Investigation every homicide that occurs and whether it was ruled justifiable. It is impossible to prove whether the laws caused the trends, but the data do indicate that homicides rose in many states that passed them, even as they declined in states without them, and that prosecutorial findings of justifiable homicide are significantly higher in those states. (Interestingly, Florida is the only state that does not report these data to the F.B.I.) Furthermore, studies have found "substantial evidence of racial disparities in justifiable homicide determinations. Regardless of how the data are analyzed, substantial racial disparities exist in the outcomes of cross-race homicides … [and] the recent expansion of Stand Your Ground laws in two dozen states appears to worsen the disparity" (Roman, 2013).

This example of variation in state laws illustrates the sociologists' point: crime is defined differently depending on time and place and culture. Stand Your Ground laws, which essentially define a killing as not murder if done under any circumstances presenting a threat, are generally on the books in states where voters support gun ownership. What act the law will regard as a crime is not universal even in the most serious of felonious actions: murder. Crime policy as set by state law varies accordingly.

Perhaps the most contentious contemporary example of the difficulties of definition is whether drug use is a crime. Drug use has generally been considered a 'victimless crime,' – along with prostitution, gambling, production, and sale of pornography, and so on – because the person engaging in the acts is said to harm only himself or herself, but laws will often define the acts as criminal if legislators believe they cause great social and moral harm to the general public. (Indeed there may be a victim, though, depending on one's view as to how harmful these private acts are to the larger society. If the public

in general is the victim of these acts, they would not be regarded as 'victimless.' Thus, alternative terms could be 'consensual crime,' or 'vice crime' in the examples given here.) Indeed there may be a victim, although, depending on one's view as to how socially or morally harmful, these private acts are to the larger society. If the society in general is considered the victim of these acts, alternative terms such as 'consensual crime' or 'vice crime' or 'morals crimes' may be preferred. That these 'morals' laws vary over time is well understood. Modern Americans may scoff at the moral crusading of the Temperance movement which advocated prohibition of the manufacture, transportation, and sale (though not the use) of beer, wine, and liquor and was successful in bringing about the passage of the 20th Amendment to the US Constitution in 1920. Although Prohibition was repealed 13 years later, the policy of demanding abstinence indeed had the effect of significantly lowering the rate of illness, deaths, and violence associated with alcohol consumption; perversely, it also had the effect of empowering gangster syndicates that built an underground booze-producing economy and fostered corruption in the law enforcement agencies that had to enforce the law (Aaron and Musto, 1981). The production and sale of alcohol was a crime in 1920 and was not a crime in 1933. Definitions of crime can shift.

The contemporary equivalent of Prohibition is 'The War on Drugs.' Although production, sale, and use of drugs ranging in intensity of effects from marijuana to heroin to psychedelics have variously been defined as against the law throughout the nineteenth and twentieth centuries, any could be 'decriminalized' by simply not enforcing these drug prohibition laws. Conversely, drug use, production, and/or distribution could be defined and prosecuted and punished as serious felonies akin to homicide or sexual assault. That is indeed what happened as the 'War on Drugs' proceeded through the late 1980s until late 2000s. Today, sentencing policy about production, sale, and use of various drugs has become generally less punitive but also widely divergent among the states and federal jurisdictions. "[A]t least 29 states have taken steps to roll back mandatory sentences since 2000 … Much of this legislative activity has taken place in the last 5 years and most changes affect nonviolent offenses, the vast majority of which are drug-related" (Subramanian and Delaney, 2014). Indeed, in 2012, the states of Colorado and Washington repealed their laws against the use of marijuana. At the same time, it became apparent that the nation's most dangerous drug abuse problem has become the use of prescription opiates, which are, of course, usually prescribed and used legally but can be diverted to recreational uses.

Definitions of business-related crime also shift over time and are subject to nonenforcement, even if they are 'on the books.' A common enraged outcry following the financial crisis of 2008 was that 'none of those guys went to prison.' However, making mortgage loans while ignoring the fact that the mortgagees were unlikely to be able to repay them – with the intent of selling the loans as worthless mortgage-backed securities to unsuspecting stock investors – was not against the law. When the economy went into 'freefall' as a result of collapsing credit markets and shrinking consumer demand, the public discovered that these mortgage practices were not subject to criminal laws; indeed, they were not even regulated closely by administrative agencies. Another example is the story of the insurance company AIG. Reckless gambling on what banks would do in credit markets, using 'credit default swaps,' caused AIG to lose $200 billion. The federal government took on the debt in a 'bailout' to prevent the nation's economy from crumbling, but none of AIG's acts had previously been defined as crimes in federal law.

Although the laws on the books have not changed much since 2008, prosecutorial discretion as to how vigorously to apply those laws operates such that actions previously overlooked will be prosecuted if they have caused great harm and are more widely publicly condemned. As Khanna points out, "One of the first things to note about corporate crime legislation is that enforcement has traditionally been quite thin – indeed it may appear largely symbolic…" (Khanna, 2004), so in this example the issue is not that the laws are not on the books, but that they are not enforced. Furthermore, from what we saw in the mortgage meltdown, most of that activity was not against the criminal law – regulatory law, perhaps, but not criminal. Thus, it is apparent that policy choices about what acts are crimes vary depending on time, place, and circumstance. Sometimes policy is quite punitive and at other times it is almost nonexistent. Setting the degree of social control a policy is expected to exert over particular acts – labeling them criminal or not, or choosing to enforce the law or not – is a political process influenced deeply by the cultural and historical assumptions of the age.

Suppressing Crime and Protecting Liberty

In liberal democracies, the omnipresent tension between preserving liberty and providing security lies at the heart of crime policy debates. The word 'liberal' derives from Enlightenment philosophy regarding 'liberty,' which social contractarians defined as the capacity to live and work freely in civil society subject to the constraints of law. The law provided the security of protection from harm by others, but it also controlled government so that it could not intrude on citizens' personal lives (Locke, 1690). Those 'personal' lives are roughly set out in the Bill of Rights, the first 10 amendments to the 'social contract' of the United States Constitution: freedom of religion, freedom of speech, freedom not to be arrested on suspicion of criminal activity unless the government has probable cause to conclude that the act was criminal and the suspect was the one who committed it, the right not to be coerced to confess to crime, freedom from being punished cruelly, and so on. These 'liberal' or 'liberty' protections must operate at the same time as government sets out to provide personal security against crime for its citizens. That liberty and security often clash is well understood, but the best way to formulate policies that will provide the greatest amount of both liberty and security simultaneously is not as easily grasped.

For example, recent controversies about the proper scope of the collection and use of data by the National Security Agency raise serious concerns about whether the federal anti-terrorism program has resulted in violation of 4th Amendment rights of US citizens. (The 4th Amendment to the United States Constitution provides "The right of the people to be secure in

their persons, houses, papers and effects, against unreasonable searches and seizures, shall not be violated ….")

Must law enforcement officers suspect that a particular person has committed a crime, such as aiding terrorists, before investigators will be permitted to gather information which might eventually ripen into sufficient evidence to constitute probable cause to arrest? This would seem to be the legal standard, but the technology of information gathering has progressed so quickly and deeply that it is now possible to track the phone calls, physical locations, and online activity of virtually all Americans. Patterns of online behaviors that might lead to knowledge about crimes such as terrorism – or, arguably, political activity or reading habits – are observable through algorithmic data-mining, even though the individuals whose activities are surveilled had not been linked to or suspected of any crime in particular at the beginning of the data analysis. Connections between phone numbers of people known to have links to terrorism and everyone those suspects have called constitute one 'hop' when all data on the contacts are gathered and examined for patterns. Next, all phone numbers connected to those contacts are also examined: the second 'hop.' The National Security Agency is said typically to make at least four 'hops' examining the phone call patterns in all phones branching from the original suspect, subsequently 'fusing' the information from a great many different data sources together around a common personal identifier such as a social security number or an email address if suspicious phone call patterns of a particular number are observed. The policy question is how to find the point at which personal freedom is preserved at the same time that security from acts of terrorism is enhanced. In this context, the question would be: "how many hops are too many, and how far can government go in fusing personal information to a particular phone number/identifier?" This problem has recently been litigated and conflicting opinions from federal district courts indicate that the issue will probably find its way to the US Supreme Court in the future. (See, e.g., the memorandum opinion in *Klayman v. Obama*, 2013.)

This issue is scarcely new. It has always been the case that law enforcement pushes to investigate and arrest, while Constitutional law demands that these activities be conducted only when controlled by liberty-preserving standards and procedures. A common way of describing this tension is to say that crime control must be accomplished under the constraints of due process (Packer, 1968). Most commentators today state that due process has been swept away in favor of a crime control apparatus that observes the forms of due process (i.e., requires probable cause to arrest, prohibits brutal interrogations, does not coerce confessions, provides the right to a jury trial) while substantively supporting crime control ideology. (Stuntz, 2011; see also Greenspan, 2014, arguing that the standard of proof 'beyond a reasonable doubt' historically required to prove criminal culpability has eroded down to the lower standard of 'preponderance of evidence' typical of administrative proceedings.) Several scholars state that crime control strategies have trumped liberty interests because actuarial risk management techniques have become the most common tools for reducing harm in all areas of contemporary life; we manage and spread risk, even the risk of crime, in much the same way as insurance companies manage and control the risk of automobile accidents. (O'Malley, 2010; see also Feeley and Simon, 1992, arguing that criminal justice agencies now operate under a 'new penology' designed to 'manage the underclass' using actuarial techniques of prediction and control.)

Some legal scholars, by contrast, tend to criticize the due process model for its very success, which led to its elimination at the hands of crime prevention. That is, due process became so cumbersome and technical that the system evolved to avoid it (Stuntz, 2011). One important example: in 1975, approximately 20% of felony cases went to trials before juries. In 2010, only 1% of them did (Galanter, 2005). A guilty plea is technically a confession to the crime, which means that the state need not meet its burden of producing evidence in public trial which proves beyond a reasonable doubt that the defendant is indeed guilty. It is generally well known that defendants often plead guilty because conviction after a jury trial will produce significantly harsher penalties than conviction from a guilty plea will (McCoy, 2005). This is a strong example of criminal justice policy evolving toward crime prevention and control at the expense of personal freedom (in this case, the right to trial).

In practice, the government has little incentive to produce laws that would evince a policy of providing both security and liberty simultaneously. When it moves too far in devising and implementing policies meant to provide security, Constitutional standards as interpreted and applied in the courts, via the doctrine of judicial review, can insert elements of personal liberties in the process. Furthermore, legislation covering security matters is drafted so as to take liberty concerns into account. In the example of surveillance of communication technologies, see 'Liberty and Security in a Changing World,' legislative standards recommended by a Presidential review panel (President's Review Group on Intelligence and Communication Technologies, 2013).

Perhaps the most well-known metaphor for describing the tension between crime control and liberty protection in the field of criminal justice policymaking is 'the net.' The state seeks to catch and control deviant people in its 'net,' and the liberty issue concerns how wide the net will be, and how small its webbed openings will be. In other words, how many people will be caught and kept in the net of the criminal control system? Policies may be seen as 'widening the net' or narrowing it and/or as 'broadening the sieve's holes' or closing them.

For example, policies about appropriate punishment following conviction – criminal sentencing in general, but also administrative procedures of particular programs such as parole from imprisonment – become more or less liberty preserving depending on how intrusive the state is permitted to be in demanding that convicted offenders submit to programs or incarceration. Julian Roberts gives an example: the net is widened when a 'community sanction' such as electronic monitoring combined with house arrest is applied "to offenders who were not at risk for a term of custody in the first place" (Roberts, 2004: 117). Supposedly for the goal of reducing reliance on imprisonment as a criminal sanction, a variety of nonincarcerative sentencing options are developed (electronic monitoring, work programs, drug treatment combined with halfway house nighttime custody, fines and restitution via restorative orders, home custody, etc.). If these options are not used instead of imprisonment, or are added on

to parole orders after release from prison, the net has widened. If judges send the same offenders who would have gone to prison to these in-community punishments instead, the net has narrowed. If an offender commits a new crime or violates a condition of the program and is sent to prison, the 'hole of the sieve' is tight; if the offender is kept in the community and program restrictions tightened, it is wider. Whether the net widens or loosens is a matter of policy choice by legislators and executive branch corrections managers.

Branches of Government that Design and Implement Crime Policy

These observations lead to the third topical issue: the exercise of state power to enforce the law. Law enforcement is the province of the executive branch of government. Law enforcement is explicitly concerned with crime control, and its agencies are the police (conducting investigations and also response to crimes that have occurred) and prosecutors. Although prosecutors are often regarded as members of the judicial branch because they are lawyers, in fact they perform law enforcement functions of criminal investigation and response to crimes, as well, when they hold criminal suspects to account through court proceedings. The prosecutorial power is widely regarded as the most powerful function of all criminal justice officials, insofar as it touches the greatest number of people and can exert considerable control over any of them. (The judiciary is also quite powerful, but judges consider only those cases which prosecutors bring to them, and prosecutors can investigate and also make agreements with suspects that are not reviewed in court.) Crime control is conceptualized as crime prevention and also response to crimes that have already occurred, and it can include social aid under a rehabilitative or restorative rubric, under the assumption that helping offenders improve their lives will prevent them from committing more crimes.

Law enforcement policy shifts over time, as do policies in all branches of government. An example is policies in local jurisdictions related to street crime. Local police traditionally have operated reactively; they respond to victims' calls for help. But police duties have always also included patrol, either on foot or in vehicles. Twenty-first century policing has evolved to emphasize crime prevention as well as response. This is often called 'proactive policing' as opposed to 'reactive.' Environmental crime prevention through 'target hardening' (i.e., improving, for example, locks and alarms) as well as installing closed-circuit television surveillance on public streets are examples of earlier crime prevention programs that public police have undertaken, but a more fundamental repurposing of patrol itself has now become more common. Stop-question-and-frisk practices, by which patrol officers confront persons on the street and ask for their identification and information about their activities, which might lead to suspicion of wrongdoing and thus to a body frisk for contraband such as weapons or drugs, have become much more common. Although the Supreme Court case of *Terry v. Ohio*, 392 U.S. 1 (1968) held decades ago that police officers may frisk suspects only if the officers believe that their lives or the lives of others are in danger, courts seldom question the legality of this practice when arrested suspects are brought before them. Nevertheless, in some jurisdictions the practice has become so controversial that residents of neighborhoods in which stop-question-frisk is a very common tactic of crime prevention sometimes protest bitterly that the stops are racially pretextual rather than rationally crime related. Federal courts may require that police policy on the matter be much more carefully controlled. (See: *Floyd v. City of New York*, Southern District of New York, decided 12 August 2013 cite not yet available.) These controversies are very similar to earlier policy debates about whether police should arrest and detain people for disorderly activities such as panhandling or drinking in public, rather than referring the problems to city agencies dealing with the homeless and addicted, on the assumption that vigorous intervention in 'quality of life crimes' will prevent more serious crime in the future. (Compare Kelling and Coles, 1996 with Harcourt, 2001.)

Of course, the executive is not the only branch of government which works on crime policy. (Criminal corrections agencies responsible for the delivery of punishment through in-community programs or incarceration are executive agencies and are discussed below.) The legislature writes the criminal code, which might be seen as a 'meta-policy.' The judiciary is more concerned with crime on a daily basis, since judges subject each case to scrutiny in the usual criminal procedures. Of course, crime policy like any other public policy is shaped by its budget. It is generally agreed that the quality and availability of criminal defense attorneys are highly correlated with the amount of public funding available. If defense attorneys were to demand that the state demonstrate the strength of its evidence more often than the current plea bargaining system allows, courts' policies about proof and speedy trial would probably change.

What Works?

Finally, which crime policies work best? Legislatures will pass laws to support those programs that are seen to be effective, and the programs will be required to design their own daily standard operating procedures (which might be regarded as policies in themselves).

The goals of crime policy are several and distinct depending on the problem to be solved, as the previous discussion of liberty and security shows. The goal may be to provide fairness in criminal adjudication, to punish effectively and humanely, to reduce crime and recidivism, or to achieve other goals. Obviously, inquiry into whether a policy 'works' or not begins with a statement of what goal it is intended to achieve. Sometimes, this is difficult.

For example, what is the goal of capital punishment? It may be to deter future murderers or it may be to provide retribution, or it may be simply to incapacitate the criminal in the most drastic way to prevent recidivism. If a state legislature determines that none of these purposes are sufficiently met to offset the costs of the death penalty (both in moral terms criticizing the state for taking any life no matter how condemnable, and in terms of the high costs of adjudicating these cases in court), the state law will not permit capital punishment. Currently, 32 state criminal codes permit the death penalty, but in only 14 have executions actually been carried out in the past 5 years.

(Death Penalty Information Center, 2014; for a history of policymaking about the death penalty in America, see Mandery, 2013.) Legislators' policy decisions are evident in capital statutes, while prosecutors' policy decisions about who to charge with a capital offense, whether to accept a guilty plea that will produce a sentence of life imprisonment without parole, and whether to give leniency to codefendants who testify against named defendants are all policy choices highlighting the nature of official discretion. If the state law does provide for the death sentence and prosecutors charge it and judges impose it, another discretionary policy choice falls to corrections officials in deciding how to carry out the sentence. (Electric chair? Firing squad? Lethal injection and if so, with what drugs?)

This is perhaps the most extreme example of crime policy, but the dynamics are the same throughout all agencies of criminal justice and can be described in the thousands of instances of policymaking within the many agencies of government. Simply put: crime policy is the outcome of official discretion to decide which course of action the state will take. That discretion itself may be more or less constrained, but it is always at the base of any decisions about what policy to set and how to implement it.

Crime, Race and Ethnicity

Abstract

The relationship of ethnicity/race to crime is a longstanding concern of criminology. Contemporary research identifies social characteristics of neighborhoods and differential treatment in the criminal justice system as the primary causes of higher crime rates among certain ethnic/racial minority groups. This article explores that research.

Introduction

A central concern of criminology is the differential patterns of crime and justice across various ethnic and racial groups in the United States. These groups are defined by the cultural (ethnic) and physical (racial) characteristics that people use to categorize and respond to themselves and to others. These categories are not always clear-cut. For example, Hispanics (or Latinos) may see themselves as members of a traditional racial category (e.g., White) or a distinct racial category (e.g., many respond Other Race in the US Census), and they will also possess a distinct ethnic identity (e.g., Puerto Rican or Mexican). Data pertaining to crime generally rely on broad categories that mask much of the variation in ethnic/racial identity, limiting analysis to comparisons among major distinctions, such as Whites and Blacks (or African-Americans). While various scholars and data sources employ different designations for ethnic/racial groups, here terms (e.g., Black and Hispanic) are used consistently for clarity.

Research on ethnicity/race focuses primarily on 'street' crimes (e.g., murder, rape, robbery, burglary) that are the mainstay of criminological research and, accordingly, are the focus of this discussion. The relationship of ethnicity and race to such crimes has constituted a major area of investigation for criminologists ever since the advent of scientific criminology during the late nineteenth century. Quite different viewpoints have characterized this work over time. For example, early research by the Italian physician/criminologist Cesare Lombroso suggested that non-European 'colored races' failed to fully evolve and, therefore, remain innately inclined toward 'savagery' (Horn, 2003). He thought that Blacks in the United States posed a social danger and were responsible for an increasing crime problem because of their inherent savagery. His ideas influenced the development of criminal anthropology in the United States, which achieved considerable popularity and helped fuel the eugenics movement in the early twentieth century. In this view, crime is heavily influenced by biologically based racial differences. These ideas were challenged by research conducted by sociologists such as Shaw and McKay (1969) at the University of Chicago. Relying on the approach of human ecology, they established that the incidence of crime is associated with certain characteristics of neighborhoods – poverty, heterogeneity, and transience – that appear unrelated to specific ethnic/racial groups. Over the past century, the viewpoint that such social factors explain variation in offending by ethnic and racial group has come to dominate the discipline, although some researchers continue to postulate that biological race contributes to criminality (e.g., Rushton, 1996).

Contemporary criminologists largely disavow a significant role for racial characteristics as causal factors in crime because commonly used racial distinctions defined by visible physical characteristics are social constructions rather than meaningful biological categories. Group categorizations based on gene distributions in populations do not correspond well with the categories of race in popular use; people with similar outward physical features used to identify race can be quite different genetically (e.g., Bamshad and Olson, 2003). Moreover, numerous studies in the tradition of the Chicago School have linked crime to the social structural and cultural characteristics of disadvantaged urban neighborhoods. Factors such as racial segregation, persistent poverty, lack of educational and employment opportunities, cultural social isolation, and discrimination appear to be the major causes of crime rate differentials among ethnic and racial populations (e.g., Peterson and Krivo, 2010; Sampson and Wilson, 1995).

Another possibility is overlooked in the focus on the causes of crime – the differential treatment of ethnic/racial minorities in the criminal justice system (CJS) may inflate crime rates for certain offenses among some groups (Tonry, 2011). Rather than representing underlying patterns of criminality, data on ethnicity/race and crime may reflect relatively greater social control of minority populations. A large body of evidence lends partial support to this proposition, but findings are not always consistent and appear to be contingent on factors such as type of offense. It appears that crime rates are explained both by variations in criminogenic social characteristics of urban neighborhoods and by differential treatment of ethnic/racial groups in the CJS.

Patterns of Crime by Ethnicity and Race

Research on patterns of crime among minority populations focuses primarily on the United States. The 2010 US Census reports that Blacks (12.6%) and Hispanics (16.3%) comprise the largest minority populations in the nation. Blacks are a diverse group, although most trace their ancestry to Africans who came to America via the slave trade. Hispanic is an ethnic identifier that encompasses numerous nationalities (those of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45002-6

Mexican origin make up 63% of Hispanics) and different racial identities (most Hispanics self-identify as White in the Census). Much of the contemporary research on race, ethnicity, and crime focuses on these two groups because of their substantial representation in the population, the various social and economic disadvantages they experience, their disproportionately high crime rates, and the discrimination they experience in the CJS.

Efforts to study the relationships of ethnicity, race, and crime are confounded by the limitations of available data. The most systematic national data consist of arrest rates and victimization surveys. Beginning in 1930, the Federal Bureau of Investigation began compiling annual data on crimes known to police, including seven serious index crimes – murder/nonnegligent manslaughter, forcible rape, robbery, aggravated assault, burglary, larceny/theft, and motor vehicle theft (arson was added in 1979) – as well as various lesser offenses (e.g., drug abuse violations). Nearly all US law enforcement agencies report known offenses occurring in their jurisdictions. These data are reported in the Uniform Crime Report (UCR), but they do not provide information on ethnic/racial identity of offenders. Arrest data are also reported in the UCR. These are broken down by four major racial categories but not by Hispanic and non-Hispanic (data on Hispanics were collected for brief periods during the 1930s and 1980s, but these offer little insight into contemporary arrest patterns). These data are limited by the exclusion of unreported crimes and reported crimes that are not cleared by arrest, which involve most crimes in many offense categories.

The other major data source on crime is the National Crime Victimization Surveys (NCVSs) conducted by the Bureau of Census for the Bureau of Justice Statistics. The surveys have been conducted since 1973. They are designed to be nationally representative and are used to make annual estimates of the number and rate of personal (rape, robbery, assault, and personal larceny) and household (household burglary, household larceny, and motor vehicle theft) victimizations. These victimization data have the advantages of capturing unreported crimes and of providing information on Hispanics, although the survey methodology also has inherent limitations (e.g., memory loss, misunderstanding about crime categories by respondents).

Black Crime

Table 1 presents race-specific arrest rates for 1990, 2000, and 2010, which include UCR index offenses (except arson) and drug violations. The rates are broken down into the four ethnic/racial categories used in the UCR. These data reveal that Blacks are arrested for major personal and property crimes at higher rates than those in other ethnic/racial categories. Caution must be used in interpreting these data given that many categories (e.g., larceny-theft) have low rates of reporting and arrest. In general, however, it appears that Blacks have disproportionately high rates of index offenses. Particularly notable is that murder rates among Blacks are several times greater than for Whites in each time period, and this offense category has high reporting and clearance rates.

It may be observed in Table 1 that murder rates, as well as those for most other personal and property crimes, declined precipitously from 1990 to 2010 (for a detailed analysis of arrest-rate trends, see Snyder, 2011). As arrest rates have declined, there has been some convergence between Black and White rates. For example, in 1990 the Black murder arrest rate was more than eight times that of Whites, but by 2010 the difference was a factor of less than six. Similarly, in 1990 the robbery arrest rate of Blacks was more than 10 times that of Whites, but by 2010 the difference was a factor of about 7. Most index crimes saw a noticeable relative reduction in Black–White arrest rates, although it is less pronounced for aggravated assault and burglary.

Another marked contrast among the ethnic/racial categories concerns drug abuse violations. Again Blacks have an arrest rate several times higher than those in other ethnic/racial categories. Although there is some convergence of Black and White drug arrest rates by 2010, this is largely attributable to a 1.5 times increase in the rate for Whites rather than the small reduction in the rate for Blacks. These observations, along with those for murder rates, underscore an important issue. Given high reporting and clearance rates for murder, there is little doubt

Table 1 Race-specific arrest rates (per 100 000 population) for selected UCR offenses[a]

	1990				*2000*				*2010*			
Offenses	*W*[b]	*B*	*AI*	*API*	*W*	*B*	*AI*	*API*	*W*	*B*	*AI*	*API*
Murder[c]	4.0	33.2	6.7	2.2	2.0	12.2	3.5	1.2	1.9	10.8	3.1	0.5

Drug abuse violations	252.0	1167.1	149.8	52.3	315.6	1034.6	224.0	70.3	378.8	1039.3	299.0	67.9

UCR, Uniform Crime Report.
[a]Offense categories include UCR index crimes (except arson) and drug violations (nonindex crime); calculations are based on data from UCR and US Census reports for the respective years.
[b]Race categories are: W – White; B – Black; AI – American Indian; API – Asian or Pacific Islander.
[c]Includes nonnegligent manslaughter.

that a disproportionately high incidence of homicide among Blacks exists. Drug violations, however, are rarely reported by citizens and enforcement largely involves proactive policing strategies, which raises the issue of whether the apparent high incidence of drug use among Blacks is a product of selective enforcement. These two offense categories highlight the complexities of explaining crime differentials and are discussed further below.

Additional evidence regarding crime among Blacks comes from victimization data. In 2005, Blacks accounted for 49% of all homicide victims (Harrell, 2007), which is comparable to UCR statistics for murders by Blacks (48.8% of total murders in 2000; 48.7% in 2010). These data reflect the intraracial nature of homicide. NCVS data show that in 2007, the total Black victimization rate (26.1) for personal crimes was higher than the rate of White victimization (20.5) (BJS, 2010). The higher rates of robbery (4.9) and aggravated assault (4.4) victimization among Blacks compared to Whites (1.9 and 3.2, respectively) are particularly noticeable. With respect to property crime, the victimization rate for Blacks (170.0) was somewhat higher than for Whites (141.9), which reflects higher rates of burglary (37.2) and motor vehicle theft (14.2) victimization among Blacks compared to Whites (25.1 and 7.1, respectively). Taken together, the rates of arrest and victimization indicate that Black communities are disproportionately affected by crime.

Explaining Index Crimes of Blacks

The substantial differences in arrest rates of Blacks and Whites for serious crimes provide fuel for the debate about the causes of Black criminality. As noted earlier, the dominant perspective in contemporary criminology is that social and economic disadvantages of segregated Black neighborhoods produce the disproportionately high rates of crime among Blacks. While data collected within individual cities lend support to that argument, the lack of data from a broader array of cities has not permitted a more definitive conclusion about the effects of neighborhood characteristics on crime until recently.

To address the issue, Ruth Peterson and Lauren Krivo (2010) conducted the National Neighborhood Crime Study (NNCS) to obtain census tract-level data on reported violent (homicide and robbery) and property (burglary, larceny, and motor vehicle theft) crimes and on social and demographic characteristics for 91 cities. The sample is representative of the US cities with 100 000 or more population. Analysis of the NNCS data reveals that whereas White neighborhoods have very low levels of economic and social disadvantage, most African-American neighborhoods have very high levels. When a composite disadvantage index is included in statistical models to explain the overall ratio of violent crime rates between Black and White neighborhoods, the vast majority of the difference between them is accounted for (although the rate in Black neighborhoods remains 65% higher than in White neighborhoods). The property crime rate for Black neighborhoods is just 10% higher than for White neighborhoods after the disadvantage index is added to the model. When the spatial characteristics (e.g., disadvantage, violent crime rate) of surrounding neighborhoods are included in the analysis, the Black violent crime rate is just 13% higher than in White neighborhoods, and the property rate is slightly lower.

These analyses provide strong evidence that structural characteristics of US cities, namely the disadvantages disproportionately borne by segregated Black neighborhoods, largely account for the exceptionally high crime rates observed for Blacks. It appears, therefore, that much of the serious crime problem that exists among African-Americans can be explained by the historical segregation of a substantial part of that population in disadvantaged urban neighborhoods (see also Massey and Denton, 1993).

Blacks and the War on Drugs

The War on Drugs, which began during President Reagan's administration, profoundly affected the Black population. The greatly disproportionate Black arrest and imprisonment rates for drug abuse violations during the past three decades would seem to suggest that drug use is a substantial problem in that population. However, that is not the case. While arrests for drug violations are much higher among Blacks, their overall use of most drugs is lower than among Whites (Tonry, 2011). For example, cocaine use (powder and crack combined) is appreciably higher among Whites than Blacks. Moreover, Blacks are not more involved than Whites in the drug trade. One reason for the higher arrest rate involves the social organization of drug distribution. The anonymous transactions in the public drug markets of urban Black neighborhoods are more susceptible to surveillance than are the personal transactions among acquaintances within existing social networks of White neighborhoods. Moreover, police stop and search Blacks more often than Whites in public places, although these contacts result in lower rates of contraband seizure (i.e., guns and drugs) for Blacks than Whites, suggesting that race per se is often the reason for stopping Blacks.

Hispanic Crime

Research on crime among Hispanics is complicated by the UCR reporting system. Most of the arrest data for Hispanics are folded into the White category, disallowing any direct comparisons with other ethnic/racial groups. However, Peterson and Krivo's (2010) NNCS included data on crime in Hispanic neighborhoods. Hispanics tend to reside in relatively disadvantaged neighborhoods compared to Whites, but the degree of Hispanic neighborhood disadvantage does not reach to that experienced by Blacks. Crime rates also occupy an intermediate position. When neighborhood disadvantage is included in statistical models to predict neighborhood crime rates, the violent crime rate remains 29% higher than in White neighborhoods, and the property crime rate is 8% higher. With the addition of spatial characteristics of surrounding neighborhoods to the analysis, the differences between Hispanic and White neighborhoods for both violent and property crimes become negligible.

Victimization data indicate that Hispanics have a slightly lower personal crime victimization rate (19.6) than Whites (see above). The Hispanic rate of property crime victimization (190.5), however, is higher than for Blacks or Whites. The higher rate of property victimization is particularly evident for motor vehicle theft (over twice as high as Whites) and theft (one and a third times that of Whites).

Hispanic Immigration and Crime

In recent years a significant debate has centered on whether illegal Hispanic immigrants (especially from Mexico) to the United States are disproportionately involved in crime. The concern about immigrant crime provided the impetus for controversial legislation aimed at controlling the alleged problem in Arizona. The 2010-law included the requirement that law enforcement officials attempt to ascertain individuals' immigration status during a lawful stop or detention and made it a misdemeanor offense to be an alien in Arizona without carrying required documents (e.g., an Arizona driver's license). The Supreme Court (*Arizona v. United States*, 567 U.S.___ 2012) ruled that key provisions of the Arizona statute are preempted by federal law, but illegal immigration and crime remain hot-button issues. While some are convinced that immigrant crime poses a serious problem, others are concerned that Hispanics are being indiscriminately subjected to racial profiling.

Criminologists question whether a crime problem actually exists. Research generally finds little evidence that immigrants are disproportionately involved in crime (for a review, see Ousey and Kubrin, 2009). Contemporary public perception of the problem is fueled in part by the large number of incarcerated Mexican immigrants. Immigrants are largely young males, mirroring the demographic categories generally associated with crime. Once the age and sex distribution of the immigrant population is taken into account, Mexican immigrants are incarcerated in state prisons at rates not much different than U.S. citizens (Hagan and Palloni, 1999). That study also found that immigrants in two US–Mexico border cities (El Paso and San Diego) are more likely to be detained before adjudication, which increases their chances of conviction and imprisonment. A longitudinal examination of the connection between immigration and violent crime rates in cities of 100 000 or more population shows that within-city change in immigration is negatively related to within-city change in violent crime rates, after important sociodemographic characteristics of the cities are controlled (Ousey and Kubrin, 2009). In other words, immigration is related to lower violent crime rates.

Crime among Other Ethnic/Racial Groups

As shown in **Table 1**, in addition to arrest data on Whites and Blacks, the UCR includes American Indian and Asian or Pacific Islander categories. These groups comprised .9% and 5.0% (4.8% Asian, 0.2% Pacific Islander) of the US population in 2010. It may be seen that the 2010 index offense arrest rates (except burglary) for American Indians are somewhat higher than for Whites, but appreciably lower than for Blacks. Drug abuse violation arrests are lower than for Whites and Blacks. Research on homicide among American Indians shows that social structural characteristics contribute to their high homicide rate (e.g., Lanier and Huff-Corzine, 2006), consistent with research on violent crime among other disadvantaged ethnic/racial groups.

All crime rates for those of Asian and Pacific Island ancestry are appreciably lower than for any other racial category. Although there is little criminological research on this population, these rates likely reflect the relatively economically advantaged position of many Asians compared to other ethnic/racial minority populations in the United States.

Differential Treatment in the CJS

The data presented above indicate the existence of crime differentials among various ethnic/racial groups. However, a critical question for researchers is the degree to which differential arrest rates reflect disparities of treatment in the CJS. While arrests and subsequent CJS decisions may be attributable to differences in legally relevant characteristics across groups (i.e., their involvement in crime), it also appears that discrimination based on offenders' extralegal social characteristics is at work. Historically, there has been considerable debate about the degree to which the more severe outcomes of Blacks and Hispanics in the CJS reflect disparate involvement in serious crime vs discriminatory treatment (Spohn, 2000).

Case Processing

While theories of crime causation have dominated the field of criminology since its inception, theoretical perspectives emphasizing the role of extralegal considerations in differential outcomes in the CJS gained greater prominence in criminology beginning in the 1960s. One such perspective maintains that crime is socially constructed by agents of the CJS. Stereotypes of crimes and offenders are said to influence decisions at various stages of the processing of defendants (e.g., Steen et al., 2005). Another approach argues that economically and socially disadvantaged defendants have relatively limited access to legal resources (e.g., pretrial release), which indirectly influences final dispositions (e.g., Holmes et al., 1996). While research consistently demonstrates that legal considerations – notably offense severity and prior criminal record – influence defendants' outcomes, these perspectives explain how social characteristics such as ethnicity/race also may influence outcomes at various stages of case processing. Insofar as differential patterns of incarceration may involve cumulative disadvantage accruing from decisions at various stages of adjudication, a process-oriented approach that considers patterns of arrest, pretrial decisions, and sentencing is necessary.

Arrest

A large body of literature indicates that Blacks and Hispanics are disproportionately stopped, searched, and arrested by police (for a review, see Smith and Alpert, 2007). These disparities exist across various regions and different types of law enforcement agencies. An obvious explanation for this pattern is the differential involvement of minorities in crime, but it appears that disparate treatment of minorities is not simply a by-product of differential offending. Historically, the racial animus of White police officers undoubtedly affected the differential treatment of minorities, but now greater representation of minorities in policing and less tolerance for overt discrimination by police departments may have reduced, but hardly eliminated, open discrimination against minority citizens. Researchers continue to document very aggressive, often legally impermissible, strategies of policing in disadvantaged minority neighborhoods (e.g., Brunson and Miller, 2006). Policymakers may deploy more police resources or implement aggressive stop and frisk strategies in minority neighborhoods, and individual officers may unconsciously engage in racial profiling irrespective of their

own racial identity (Smith and Alpert, 2007). These practices may increase discretionary stops of minority citizens, which, in turn, may increase arrest rates for crimes such as drug possession.

Pretrial decisions

Once an arrest takes place, several important decisions occur before formal adjudication occurs. The first is the setting of bail. The constitutionally sanctioned purpose of bail is to ensure a defendant's appearance at subsequent proceedings, except in cases where the defendant is a flight risk or poses a significant danger to the community. Yet, bail setting in urban jurisdictions, where most criminal cases are adjudicated, often involves perfunctory consideration of a defendant's background and ability to make bail. An analysis of a sample of formally charged felony defendants in the 75 most populous counties in the United States shows that Black and Hispanic defendants obtain less favorable pretrial release decisions and outcomes (released or not released) compared to Whites after controlling legally relevant factors such as criminal history (Demuth, 2003). Minority defendants may be disadvantaged in bail decisions because of stereotypes about criminality or a relative lack of economic resources to make cash bail. When defendants are not released prior to adjudication, final case dispositions may be adversely affected, although research on this issue remains limited and provides mixed findings (see, e.g., Holmes et al., 1996). Pretrial detention may, for example, reduce family stability or result in loss of employment, which constitutes ties to the community that are considered in subsequent decisions about probation vs imprisonment.

Charging decisions and plea negotiations have also been identified as possible sources of discrimination against minority defendants, but the influence of ethnicity/race on these decisions has received limited attention from researchers. Available studies provide mixed evidence that ethnicity/race affects these outcomes, but the paucity of research precludes any definitive conclusions (for a review, see Shermer and Johnson, 2010).

Sentencing

One of the most extensively researched and debated issues regarding ethnicity/race and crime is disparities in sentencing. Studies of sentencing focus on two outcomes: probation vs parole or length of sentence. The former in/out decision is particularly important because incarceration conveys significant disadvantages compared to release on probation, which allows continued employment, facilitates stable family relationships, and averts the difficult conditions of prison life. Both of these decisions are heavily influenced by legal considerations, notably defendants' prior criminal histories and present offenses, as expected. However, after controlling legally relevant variables, does ethnicity/race affect sentencing decisions?

Cassia Spohn's (2000) systematic analysis of the literature answers that question in the affirmative. For state courts, she reports that 55.5% of reported statistical effects show that Blacks, and 41.7% that Hispanics, are more likely than Whites to be sentenced to prison than to probation. Relatively few demonstrate that Black or Hispanic defendants receive longer sentences in state courts. At the federal level, some research finds evidence that Blacks (42.8% of reported effects) and Hispanics (also 42.8%) are more likely to be sentenced to prison, and most show that Blacks (66.7%) but not Hispanics receive longer sentences on average. In addition to the main effect of race, many of the studies Spohn reviews consider the contexts in which ethnicity/race influences sentencing. She identifies four patterns of contextual effects reported in the literature: (1) certain combinations of ethnicity/race and other extralegal offender characteristics (e.g., employment status) produce greater disparity than ethnicity/race alone does; (2) process-related factors (e.g., pretrial detention) disadvantage minority defendants at sentencing; (3) some combinations of offender–victim race (i.e., Black offender–White victim) may produce harsher sentences; and (4) sentencing differentials may depend on the type of crime (e.g., minorities may be sentenced more harshly for drug offenses). While noting that findings are not entirely consistent and significant effects of ethnicity/race are sometimes modest, she concludes that the disproportionate incarceration of minorities reflects more than legally relevant considerations. A subsequent meta-analysis of sentencing research similarly concludes that most statistical effects indicate that Blacks are punished more severely than Whites (Mitchell, 2005).

Incarceration

Data on incarceration in the United States reflect the patterns of arrest and adjudication described above. The higher arrest rates and probabilities of prison sentences for Blacks and Hispanics are reflected in much higher incarceration rates per 100 000 males (3119 and 1193, respectively) compared to White males (487) in state and federal prisons in 2009 (West et al., 2010). (Female incarceration rates are much lower than males, but somewhat smaller ethnic and racial disparities still exist.)

Focusing on the Black–White disparity in incarceration rates, Tonry (2011) demonstrates that since 1950 Black incarceration rates per 100 000 increased dramatically compared to White rates, and stood at roughly eight times greater by 2008. Part of the higher incarceration rates for Blacks is a reflection of higher arrest rates, particularly for violent crimes that often result in imprisonment; however, a sizable part of the higher rates of incarceration remains unexplained by arrest rates. Moreover, Blacks are arrested at higher rates for the personal offenses of robbery and aggravated assault than their involvement in those offenses would predict. Of particular significance is the greatly disproportionate rate of incarceration of Blacks for drug offenses, which is at odds with their patterns of use and distribution. Rather than reflecting differential involvement in crime, the rate is a product of the harsher sentence structure for drug offenses more common among Blacks (e.g., longer sentences for crack compared to powder cocaine under federal sentencing guidelines) and the practices of police (e.g., racial profiling) that result in much higher arrest rates for Blacks.

It appears that Hispanics are also disproportionately incarcerated relative to their involvement in crime. Research shows that, after controlling for legally relevant factors, young Hispanic males are more likely to receive a prison sentence (Spohn and Holleran, 2000). Moreover, relatively large numbers of Hispanics are incarcerated in state prisons for drug offenses (see West et al., 2010), although Hispanic rates of drug use are generally lower than that of Blacks or Whites (Warner et al., 2006).

The Death Penalty

Certainly the death penalty is the most severe and irrevocable criminal sanction, and its use highlights concern about ethnic/racial injustice in the CJS. At the end of 2009, there were 3173 prisoners under sentence of death in the United States (Snell, 2010). Of those, 56.1% were White and 41.5% Black (Hispanics are included in these calculations). Thus, the proportion of Blacks on death row is 3.3 times their representation in the US population, whereas the representation of Whites on death row is substantially lower than in the overall population (75.1%). Hispanics make up 13.5% of death row inmates, which is somewhat below their representation in the population in 2010. Since 1977, 1188 prisoners have been executed in the United States. Of these, 56.6% were non-Hispanic Whites, 34.6% were non-Hispanic Blacks, and 7.7% were Hispanic (all others were 1.2%).

Supreme Court decisions of the past four decades call attention to the racial disparity involving Blacks on death row. In *Furman v. Georgia* (408 U.S. 238, 1972), the Court narrowly ruled that the arbitrary, capricious, and discriminatory nature of the imposition of the death penalty violated the prohibition against cruel and unusual punishment of the Eighth Amendment, but the question of racial discrimination in its application was not the central issue in the ruling. Subsequent decisions allowed reinstatement of the death penalty so long as juries consider statutorily defined aggravating and mitigating factors in reaching their decisions (*Gregg v. Georgia*, 428 U.S. 153, 1976), but disallowed the use of the death penalty in rape cases because rape victimization does not involve 'serious' injury, and the death penalty is grossly disproportionate to the severity of the crime (*Coker v. Georgia*, 433 U.S. 584, 1977). Historically, the death penalty for rape had been applied almost exclusively in cases involving Black defendants and White victims, but this was not the central issue in the Court's decision (both the defendant and victim were White in the *Coker* case).

The Supreme Court directly confronted the issue of racial discrimination in the death penalty in *McClesky v. Kemp* (481 U.S. 279, 1987). Based on a sophisticated statistical study conducted by David Baldus and associates, the case of Warren McClesky (a Black defendant convicted of killing a White police officer) was appealed on the grounds that it violated provisions of the Fourteenth (equal protection) and Eighth (cruel and unusual punishment) Amendments. The study used to support these claims demonstrated that, after controlling numerous legally relevant factors, cases involving White victims were several times more likely than those with Black victims to result in a death sentence in Georgia (defendants' race was not a factor). Little disparity existed at the extremes of the aggravation continuum, with pronounced differences observed in cases falling in the midrange of aggravation, where cases might go either way. Although acknowledging the validity of these data, the Court affirmed McClesky's death sentence in a controversial 5–4 decision. It ruled that the statistical data did not provide clear proof that racial animus influenced the sentence of death in McClesky's case, which established the standard to prevail on appeal. Given that seemingly race-neutral court proceedings can mask race-based decision making, the ruling set a very high bar for successfully challenging death penalty sentences by requiring case-specific evidence of discrimination.

While the standard set in the *McClesky* case makes it more difficult for death penalty appellants to prevail, the Supreme Court has subsequently prohibited the use of racial criteria when credible evidence specific to the case at hand is presented. In the case of *Miller-El v. Cockrell* (537 U.S. 322, 2003), the Court held that the use of peremptory challenges to systematically eliminate Blacks from a capital murder jury violates the equal protection clause of the Fourteenth Amendment. In this instance, the statistical evidence of discrimination during *voir dire* (91% of Blacks eligible to serve on the jury were stricken by peremptory challenge) was specific to the case of Miller-El, and in the view of the Court the process of questioning prospective jurors also demonstrated purposeful discrimination by the prosecution in exercising peremptory challenges.

As it stands today, minority defendants will rarely succeed in appealing a death sentence on the grounds of racial discrimination because of the challenge of providing credible evidence of purposeful discrimination during court proceedings. Legislative and executive actions are a more likely avenue of relief from discriminatory practices, particularly given that the Supreme Court maintains legislatures are the appropriate venue for addressing the issue (see *McClesky v. Kemp*). Former Illinois Governor Ryan reluctantly commuted all death sentences in the state before leaving office in 2003, because of the evidence of racial discrimination, procedural irregularities, and wrongful convictions. Such intervention remains the rare exception, however, and it appears likely that the death penalty will continue to disproportionately impact minority defendants for the foreseeable future. Death penalty opponents remain particularly concerned about wrongful convictions. The Death Penalty Information Center reports that between 1973 and 2012, 142 death row inmates were exonerated, of whom 50% were Black.

Conclusion

The relationship of ethnicity/race to crime and justice has been a preoccupation of criminologists since the founding of the field. This article demonstrates that the problem is complex. Arrest and victimization data suggest that America's largest minority groups – Hispanics and Blacks – have high rates of serious crime relative to Whites. A substantial body of research supports the proposition that the disadvantaged conditions of Black and Hispanic neighborhoods explain many of these differences. Another body of research provides evidence that Blacks and Hispanics experience discriminatory treatment in the CJS, which inflates their apparent involvement in some crimes, notably drug violations. Taken together, criminogenic conditions of urban neighborhoods and discriminatory treatment in the CJS produce higher rates of imprisonment for Blacks and Hispanics.

This article outlines the major issues involved in the study of crime, justice, and ethnicity/race, but there are important intricacies that are beyond its scope. For example, there are extralegal activities of the CJS that do not influence the production of crime rates but adversely impact minority communities, create tensions with CJS agents, and undermine

the legitimacy of the system. The disproportionate use of excessive force by police in minority communities epitomizes the problem (e.g., Holmes and Smith, 2008). In addition, the focus of this discussion is limited to the United States. Research on other industrialized nations suggests that the patterns of crime and justice discussed here occur in many other nations as well (Tonry, 1997; Gabbidon, 2010). Studies of other nations remain sparse compared to the United States, however, partly because of limited availability of reliable data on ethnicity/race, crime, and justice. Another issue involves the social policy approaches that have been taken to address the problem. The piecemeal solutions commonly advocated by criminologists and policymakers will likely have little impact because they do not address the underlying problem of a racially and ethnically stratified society (Holmes and Smith, 2008; Peterson and Krivo, 2010). Clearly, the connection of crime, justice, and ethnicity/race will remain a critical area of criminological investigation for the foreseeable future.

Abstract

This article summarizes theoretical and empirical developments and trends in the sociology of crime. The history of the field is reviewed first, followed by discussion of its primary methods, data sources, and levels of explanation. Attention then turns to the social distribution of crime, dominant theoretical traditions, and issues of crime control. We close with brief comments concerning continuity and change in the contexts and processes associated with crime.

Introduction

Early studies of the sociology of crime were often combined with study of other phenomena such as suicide, juvenile delinquency and dependency, poverty, and child abuse (Short, with Hughes, 2007). Although efforts to understand and control these disparate phenomena have elements in common, separate disciplinary approaches to their study soon developed. Boundaries between and within the social and behavioral sciences have become less distinct, however, as knowledge has accumulated and research programs have become more interdisciplinary. Crime control programs have also changed, often in response to discoveries and insights from the social and behavioral sciences. Relationships between sociological scholarship and crime control programs have been controversial but important to both scholarly and control efforts.

History of Sociological Issues in the Study of Crime and Criminals

The sociology of crime is marked by controversy, beginning with definitional issues. The focus, on law – law making and breaking, lawbreakers and their victims, and the control of law breaking and lawbreakers – serves as a unifying theme for an otherwise extremely diverse discipline. This theme is increasingly challenged, however, by the continually evolving nature of criminal and regulatory law, the diversity of substantive interests associated with expansion of the scope of behaviors defined as criminal, and differences within and between nations in law enforcement and justice practices. Such centrifugal tendencies in the sociology of crime have occurred even as study of crime has become more interdisciplinary, less identified as a special field of sociology, and more closely related to legal and extralegal crime control efforts. Diversity and change, in turn, have made the full range of the sociological *oeuvre* more relevant to the explanation of crime.

The sociology of crime is often traced to the emergence, in the nineteenth century, of the positivist view that crime and criminals could be objectively identified and measured. Attracted to the positivist thinking of Darwin, the Italian military physician Cesare Lombroso studied physical stigmata among Italian prisoners and soldiers. His attribution of crime to atavism, i.e., reversion to an earlier biological stage of development, was later modified to recognize the influence of social and economic circumstances and of mental illness.

Emphasis on social factors was inspired by journalistic accounts of social conditions associated with crime and child dependency and by systematic research conducted by André-Michel Guerry (1833), Adolphe Quetelet (1831, 1835), Émile Durkheim (1951/1897), and Gabriel Tarde (1886) documenting regularities in the distribution of social phenomena. Durkheim's insistence that social facts such as suicide and homicide rates were *sui generis* drew a boundary between sociology and psychology that profoundly affected the development of both disciplines.

As one of the earliest disciplines to include crime and criminals among its research and theoretical interests, sociology continues to be the primary discipline of many criminologists. Increasingly, however, sociologists of crime are associated with interdisciplinary research programs and criminal justice departments. Substantive interests also continue to evolve, largely in response to changing social conditions and legal criteria. Many white-collar crimes involve violations of regulatory law, for example, requiring relaxation of the stipulation that crime is defined as violation of criminal law. Post–World War II developments in international law defining war crimes, genocide, and other human rights violations further broaden the scope and interdependency of law and the social sciences. The complexity of such phenomena has spurred a variety of interdisciplinary sociolegal efforts and innovative methodologies and theoretical approaches. Sociologists remain at the forefront of such efforts (Hagan and Rymond-Richmond, 2009; Savelsberg, 2010).

Issues of Method, Measurement, and Levels of Explanation

Because crime consists of a very large number of heterogeneous criminal acts, no single measure or methodology can fully capture its nature. Historically, the full armamentarium of methodologies of the social and behavioral sciences has been employed in pursuit of measuring and understanding crime and criminals. We begin with attempts to measure crime based on actions of law enforcement and other criminal justice agencies.

Many countries now collect data on crimes known to the police, persons arrested, persons appearing before juvenile and adult courts, and persons convicted and sentenced to various forms of correctional sanctions. However, because data collection and reporting systems reflect the laws and practices of the jurisdiction with which they are associated, they vary considerably in scope and quality. Another challenge is that official systems of common crime reporting are designed primarily to serve institutional purposes, such as documenting police or court activity, justifying budget requests, and evaluating institutional performance, rather than to satisfy scholarly interests.

A great deal of scholarly as well as official effort has gone into standardizing definitions and reporting systems in order to enhance their comparability and research usefulness. Principles guiding efforts to establish these systems focus primarily on distinctions between *crimes against persons* and *property crimes* and on assumptions concerning data reliability. The further removed from the behavior being reported, the less reliable it is assumed to be as a measure of that behavior; and because officials such as the police must rely on victims and others to report most crimes, crimes that are likely to be reported are the most reliable as measures of those crimes. Thus, measures based on serious *crimes reported to the police* (or in surveys of victims of crime) are favored when the object of study is the distribution of crimes. For purposes of studying offenders, data on *persons arrested* for serious crimes are regarded as superior to data on persons incarcerated for those crimes.

Dissatisfaction with official data sources has motivated the search for other measures of crime. *Self-report* surveys of individual involvement in criminal/delinquent behaviors and of victimization were developed in the US in the mid-twentieth century and continuously are being refined and solicited from better samples, over time, and in many countries. Data collection using this technique requires that sampled respondents estimate, retrospectively or prospectively, their offending and victimization experiences within a specified time frame. Convergence with official data sources usually is interpreted as evidence of differential behavior rather than discriminatory police treatment of racial/ethnic minority groups and lower-class populations. Self-reports have been criticized, however, for focusing disproportionately on trivial offenses, rather than on more serious forms of crime included in official data (Elliott and Ageton, 1980).

Because of their power and relative ease of administration and analysis, self-report survey research methods are the primary basis of most measures of official, self-, and victim-reported common crime. Self-reports are also employed in many tests of theories advanced to explain crime and in evaluations of the effectiveness of crime-control programs. Extending decades of findings based on cross-sectional research, *longitudinal* designs that follow participants over time have significantly enhanced understanding of the causes and consequences of crime throughout the life course.

A primary weakness of self-reports is that they are subject to multiple forms of distortion and error, including problems of recall and respondent exaggeration. Because they focus primarily on individuals, self-reports also omit crucial information about the micro- and macro-social contexts of crime and offending. Although typologies of criminal behavior systems have been proposed based on ethnographic studies of criminal techniques, careers, and lifestyles, none has succeeded in addressing the full range of criminal behavior. Importantly, self-reports and other research methods have demonstrated that most common crimes are committed not by specialists but by persons who vary the crimes they commit, contingent on their needs, abilities, opportunities, and internal and external constraints. Such versatility in offending poses special challenges to efforts to control crime through selective incapacitation of specific *types* of offenders.

Historically, the primary data employed by sociologists have been official *crime rates*. This *macrosocial* level of explanation seeks to determine what it is about groups, organizations, institutions, neighborhoods, and communities – their structural conditions, cultures, and subcultures – that leads to aggregate differences in crime and other social problems. Sociologists who focus on the *individual* level of explanation, by contrast, study the effect of social structural and cultural factors, social interaction, and learning experiences on individual behavior. They differ among themselves, however, in the extent to which they assume crime to be innate or the product of learning in the course of life experiences, i.e., 'persistent heterogeneity' in the population versus 'state-dependent' offending (cf. Akers, 1998; Gottfredson and Hirschi, 1990). A third level of explanation, the *microsocial*, focuses on criminal behavior as a function of the characteristics of situations and ongoing interaction among social actors. Arguably, this level of explanation may serve as one means to bridge the macro- and individual-levels of explanation. Research and theory at this level are based largely on ethnographic and other means of directly observed behavior, including laboratory experiments (Horne and Lovalgia, 2008).

The Social Distribution and Explanation of Crime

The basic data for sociological explanations of crime rest heavily on how crimes are distributed among such social categories as age, gender, social class, racial, and ethnic status, over time and in differing social and cultural locations. Most common crime in all modern societies is committed primarily by young males between the ages of 15 and 25, for example, and is concentrated among those who are disadvantaged by economic and/or racial and ethnic status (Peterson, 2012). Two types of crimes are major exceptions: (1) the aforementioned 'white-collar' crimes, first identified as crimes committed by corporations or persons of high status but later focusing primarily on violations of fiduciary responsibility or public trust; and (2) the broad spectrum of crimes included under the rubric of genocide, human rights violations, terrorism, and war crimes. The distinguishing character of these exceptions is that neither is encompassed by criminal law, the former because its legal status is established in regulatory as well as criminal law, the latter because it is a product of international law as well as the criminal statutes of nation states. The *consequences* of these crimes have evolved in direct relationship with legal definitions and social control actions within and between nations.

These and other expansions of legally proscribed behaviors have made the study of crime more truly interdisciplinary and

even more closely allied with law and its enforcement. Although sociologists are among the most persistent and innovative in this respect (see, e.g., Sampson, 2012; Tittle, 1995; Wikström, 2012), extension of criminal behaviors beyond common crimes, interdisciplinary collaborations, and methodological innovations make for an extraordinarily complex mix of explanatory approaches.

Several early strands of sociological research nevertheless form the basis of much current theorizing about crime. The first, building on the earlier work of the moral statisticians, sought to establish and interpret the social distribution of crime and delinquency. Following the 'Chicago School' framework of sociological and ecological theory developed by Thomas and Znaniecki (1920) and Park and Burgess (1924), Clifford Shaw and his associates (Shaw et al., 1929; Shaw and McKay, 1942) related crime and delinquency rates to social conditions in community areas in the city of Chicago and elsewhere. Their chief finding – that rates of delinquency were highest in local communities characterized by poverty and high rates of population heterogeneity and turnover – and the theory advanced to account for it – social disorganization and its successors – remain of vital importance (Sampson, 2012).

Fundamentally a control theory, social disorganization theory hypothesized that socially disorganized areas lacked the means of formal and informal social control. At both macrosocial and individual levels, the basis for control lay in processes considered to be vital to the supervisory capabilities of communities, viz., population turnover and heterogeneity, which weaken social institutions, networks of primary relationships, and channels of communication.

Although study of the social distribution of crime took on a life of its own, social disorganization theory was soon challenged by research documenting highly organized groups and institutions in communities with high rates of crime and delinquency (Suttles, 1968; Whyte, 1943; see also Patillo, 2007). Revisions of the theory thus focused on the nature of relational networks in these organizations and institutions and on their ability to mobilize internal support for goals such as crime control (Bursik and Grasmick, 1993; Sampson, 2012). Complementing and extending William Wilson's (1987) highly influential account of the 'truly disadvantaged' urban poor, this *systemic* perspective once again brought together scholarly work on social problems such as public health, cognitive development, drug abuse, and initiation of sexual behaviors as well as a variety of types of crime.

The systemic perspective advanced by Sampson and colleagues extended observations by James Coleman (1988) and others regarding social capital to demonstrating that 'collective efficacy' – intergenerational closure and reciprocal exchange in support of shared control of children – was effective in controlling youth violence. Importantly, close interpersonal relationships were not the primary basis for this finding; most important, rather, were mutual trust and willingness to intervene in common pursuit of neighborhood social control.

The theory of collective efficacy has been supported for problems other than crime and in places other than Chicago, although Sampson (2012: p. 167) notes that "Latin American countries may prove to be the exception." Moreover, contrary to Wilson and Kelling's (1982) 'broken windows' thesis, which attributes crime to objective signs of disorder and the message sent to potential offenders that neighborhood social control is lacking, collective efficacy and historically shared (and often racially tinged) neighborhood perceptions and meanings have been found to predict crime and poverty rates better than either prior crime or observed physical and social disorders (Sampson, 2012). The broken windows thesis nonetheless has profoundly influenced urban policy, as evidenced by recent police crackdowns on 'public incivilities,' such as loitering, vandalism and other petty crimes, and hooliganism.

A second major line of theory developed from symbolic interaction foundations and observations of the group nature of delinquent behavior and the effects on delinquent boys of legal definitions and enforcement actions. Case studies suggested ways in which children learn delinquent behaviors from one another and the manner in which, through encounters with the law and other authority figures, they learn they are *defined* as delinquent. Evidence of this sort led Edwin Sutherland (1939) to focus on the process by which individuals become criminals, a process he called 'differential association.' Recognition that definitions and labeling as criminal (in law, in interaction with others, and by authority figures) had behavioral consequences supported social learning, labeling, and microsocial perspectives stressing the importance of interactions with others in the course of socialization and in the production of particular behaviors. Sutherland, reacting against multifactor theories that mechanistically related factors associated with offending as 'causes' of crime, applied differential association to crimes that were significantly different from common crime, notably white-collar and professional crimes. Extension of the theory to differential social organization addressed macrosocial issues and enhanced application to sociological interests in groups, organizations, and institutions.

Yet another major sociological perspective on crime causation appeared with the publication of Robert Merton's (1938) seminal theory of 'Social structure and anomie,' which focused on the consequences of disparities between culturally emphasized goals and structural limitations on the means for their achievement. Elaborating Durkheim's concept of anomie, Merton noted that the cultural emphasis on achievement of economic success posed special problems for those who were disadvantaged as a result of their social class, racial, or ethnic status. He predicted that, for these populations, the most likely 'modes of adaptation' were 'innovation' using illegitimate means or complete rejection of cultural goals (e.g., 'retreatism' through participation in a drug use subculture), as opposed to 'conformity' with conventional rules of behavior.

Theoretical elaboration of anomie theory, as Merton's formulation has come to be known, has taken a variety of forms. Cloward and Ohlin's (1960) 'opportunity theory' joins anomie theory with both social disorganization and differential association to explain variations in delinquent subcultures. Messner and Rosenfeld (1994) theorize that the domination of institutional life by economic institutions weakens the ability of the family, school, and other institutions to control crime. Additionally, the individual-level counterpart to their systems level theory, institutional-anomie theory, implies that "the risks of committing violent crimes will be high for actors: (1) who prioritize economic roles over non-economic

roles (perceptually and behaviorally); (2) who are insensitive to the moral status of the means of action; and (3) whose enactment of economic roles is high on the 'marketness' continuum" (Messner et al., 2008: p. 174). Still others shift the focus of Merton's formulation to individual strain, viewing crime as a means for reducing psychological strain caused by failure to achieve a variety of goals, such as autonomy, status, respect, and reciprocity in relationships with others (Agnew, 1999).

While much sociological theory about crime continues to be based on these theoretical traditions, methods and perspectives that are not explicitly tied to them may serve as important conceptual bridges. 'Routine activities,' a macrolevel perspective, explains rates of crime in terms of the convergence of motivated offenders, the absence of capable guardians, and suitable targets for criminal victimization (Cohen and Felson, 1979). Similarly, at the microsocial level, the routine activity theory of general offending (Osgood et al., 1996) and the 'group process' perspective (Hughes and Short, 2005; Short and Strodtbeck, 1965) seek to identify mechanisms – such as status management and time spent in unstructured and unsupervised socializing with peers – that produce different types of crime under varying conditions.

As support for large-scale data sets, multimethod studies, and experimental programs designed to control crime increases, and compensating strengths and limitations of research methods become apparent, theories at each level of explanation are enriched and the efficacy of policy evaluations strengthened. Sampson demonstrates that findings from field experiments oriented toward individual choice and behavior, for example, neglect important neighborhood- and community-level effects (cf, Ludwig et al., 2008; Sampson, 2012). Using a variety of methodologies, he develops the argument that "neighborhoods, ecological, and other collective phenomena demand their own measurement" – ecometrics, in contrast to psychometrics, which focus on individual differences – "since they are not stand-ins for individual-level traits" (2012: p. 60). By this logic, even findings from laboratory experiments, long considered to be the 'gold standard' of research, require contextual specification.

Issues Related to Crime Control

Crime control brings the sociological study of crime full circle, back to the law. The effects of law, law enforcement, and the imposition of legal sanctions on offenders and others are major sociological concerns. Although the central assumption of deterrence theory – i.e., that human beings are rational actors whose criminal behavior can be influenced by punishment – remains at the heart of many modern systems of law and justice, few firm conclusions have resulted from extensive research on the effects of legal sanctions on criminals (general deterrence) or on those who might offend (specific deterrence). Public concern with rising crime rates during the second half of the twentieth century resulted in higher rates of incarceration of convicted offenders which, despite falling crime rates, accelerated during the last quarter of the century. A National Research Council report that concluded that increments of crime control from incapacitation of offenders were modest (the size of the inmate population in the United States doubled over a decade, resulting in an estimated reduction in crime of 10%), extremely expensive, and socially destructive remains valid (Blumstein et al., 1986). Evaluations of other 'get tough' measures of crime control reach similar conclusions.

As crime increasingly has become an issue of political contention, the relationship between knowledge about crime, criminals, and crime control has become controversial among scholars, criminal justice professionals, and the public (Garland and Sparks, 2002). Efforts to bridge these sometimes-conflicting interests nevertheless continue, theoretically and in the form of experimental programs supported by governmental agencies in many countries. A prime example is Jon Braithewaite's (1989) Reintegrative Shaming Theory and related 'restorative justice' practices involving offenders, victims, and criminal justice and community members.

Challenges of Change and Continuity

Expansion of behaviors defined as criminal requires close attention to legal definitions and mechanisms of discovery, as well as enforcement options and practices. Major developments have occurred in international law and tribunals designed to control offenses, such as trafficking in prostitution, illegal migration, offenses committed by global corporations, and state involvement in genocide, war crimes, and human rights violations (Hagan and Greer 2002; Savelsberg, 2010). Traditional distinctions continue to change between individual and corporate behavior defined as crime and in the behavior of nations that, although harmful to citizens of those nations, previously was considered beyond the purview of other nations. In addition, new laws and new rules evolve as global markets alter commercial activity.

Rapid social change, driven by advances in science and technology, creates new opportunities for crime even as it enhances crime control efforts. Communication and data transfer technologies, for example, increase opportunities for inter- and intra-agency collaboration while exposing these agencies to cybercrimes and other security breaches. New social media facilitate formation of interest groups and other collective behaviors while ironically promoting individual interests. Other technologies, such as nuclear and biotechnologies, lend themselves to widespread victimization by blackmail or terrorist attack.

These and other changes require conceptual as well as methodological and measurement innovation, as has occurred with social network analyses as well as multilevel modeling, both of which have raised new questions and informed old debates at the macrosocial, individual, and microsocial levels of explanations. There is, however, continuity as well as change in the contexts and processes that produce and reproduce crime. The challenge for sociologists of crime, lawmakers, and criminal justice scholars and professionals is to recognize and account for these diverging influences.

Crime Trends and Debates

Abstract

The reasons offered by criminologists for the greatest crime decline in the twentieth century, occurring between the early 1990s and 2000, have been varied and have led to a number of debates in the field. The crime decline during this period, explanations offered to account for this trend and related debates are the focus of this article. We discuss the demographic influence of age structure and ethnic immigration, incarceration, police forces and strategies, the waning crack-cocaine markets, the economy and abortion laws. No one of these by itself can account for the crime decline; but they all likely contributed to some extent.

Crime trends capture the attention of the media, public and politicians who demand to know what drives criminal behavior. It is the challenge for criminologists to account for changes in crime rates over time. When crime rates across the U.S. began climbing in the 1960s and into the 1970s, a number of criminologists accounted for this as the result of the relatively large baby boom population 'coming of age' – that is, the crime-prone ages of juveniles and young adults. This explanation seemed to account for a great deal of the variation in crime trends during that period. The crime trends of the mid-1980s were more baffling. During a period when the baby boom generation was 'aging out' of crime-prone years, the crime rate began rising once again. These rising crime trends also were occurring during a period when 'get tough on crime' policies had been implemented and a growing proportion of the adult population was being incarcerated. In retrospect, many criminologists agreed that, in large part, the increasing crime trends in the 1980s and early 1990s were due to the crack-cocaine trade and to gun-carrying youth who had been indoctrinated into the drug trade especially after many adult drug traffickers were arrested and imprisoned. The reasons offered by criminologists for the greatest crime decline in the twentieth century that occurred between the early 1990s and 2000 have been varied and have led to a number of debates in the field. The crime decline during this period and related debates are the focus of this article. Homicide is the primary crime type used for this discussion as it represents the most serious and best measured of street crimes, and the FBI's Uniform Crime Report is the source for these crime data.

Crime Decline: Trends and Patterns

Regardless of the data source – either the Federal Bureau of Investigation (FBI)'s Uniform Crime Reports or the National Crime Victimization Survey, index crime rates declined more than 40% between the early 1990s and 2000 to lows that had not been realized since the mid-1960s. This plummeting trend represented the most prolonged and the greatest magnitude of decline in crime since 1933 when the FBI began keeping record of national crime rates. **Figure 1** displays homicide and robbery trends for the period between 1973 and 2010 (U.S. Department of Justice). These predatory crime rates share remarkably similar trends over this period. Though not so closely shared among other serious crime series, all of the major index crimes declined during the last decade of the twentieth century.

Figure 1 shows that the two decades leading up to the crime decline were characterized primarily with an oscillating pattern. Homicide peaked in 1980 at 10.2 per 100 000 population – its highest rate in the twentieth century, then fell 23% in the next 5 years to 7.9. Between 1985 and 1991, the homicide rate rose almost 25% to 9.8. Unlike homicide trends, robbery peaked in 1990, otherwise mirroring the homicide pattern since 1980. Since 2000, the end of the great American crime decline, these rates stabilized through 2007 after which they declined until 2011, our latest available data point – dropping about 20%.

Remarkably, these general trends were not solely driven by a few of the largest U.S. cities but were found in cities across the country although the magnitude of the crime rates varied across cities (McCall et al., 2011). City-level studies of this period found that larger cities were more likely to exhibit this pattern and that the timing of the rise and fall of crime rates was earlier for more highly and densely populated cities with higher levels of deprivation (Messner et al., 2005). Messner and his colleagues (2005) also found a geographical pattern among those cities following the national trend – that is, the upturn in homicide rates began in the early 1980s on the west coast and the downturn ensued among east coast cities with patterns reflecting a dispersion of effects.

The close parallel between the homicide and robbery series shown in **Figure 1** suggests that common forces drive these trends, but criminologists have yet to arrive at any consensus on what these causal influences may be. The structural and situational factors that have been proposed as plausible drivers of these trends and related scholarly debates are the subject of this article. Before moving to those forces, we provide a brief discussion of the age- and race-specific homicide trends between 1980 and 2008.

Age-Specific Homicide Offending Trends

By disaggregating the total homicide rates shown in **Figure 1**, we discover that certain age groups, in particular, were driving these crime trends. In **Figure 2**, age-specific homicide offending rates for select age groups are displayed (U.S. Department of

Justice, 2011). The distinct patterns among these age groups are quite striking as the younger populations exhibited remarkable changes in their homicide offending patterns. In particular, the 14–17 year olds began the period with rates comparable to the relatively lower rates of the 35–49 year olds, but then by 1988, surpassed the rates of the typically higher homicide offending rate group, the 25–34 year olds, and maintained that higher rate until 1999 – toward the end of the crime decline.

The highest offending group is the 18–24 year olds with the steepest growth and decline in their homicide trends during this 30-year period – almost doubling between 1984 and 1993 (from 21.9 to 43.1) and then falling by 42% to their low of 25 per 100 000 in 2004. The youngest age group saw similarly dramatic swings, beginning in 1984 with homicide rates at 9.3 and tripling by 1993 when homicide rates hit a high of 31 per 100 000 14–17 year olds. These rates grew as many young people were affected or caught up in the crack-cocaine markets and began arming themselves with handguns. Their homicide rates then dropped below the 1984 rates to their low of 8.9 in 2003. Interestingly, the two older age groups, 35–49 and 50 years and older, realized stable or decreasing homicide trends over 72% of this 30-year period. There are no clear-cut answers

Figure 3 Race-specific (White and Black*) homicide-offending rates, 1980–2008. *Note: Black homicide offending rate divided by 5. Source: Department of Justice, FBI's Uniform Crime Reports.

to explain these shifting violent crime rates, and more puzzling to criminologists is what accounted for the unanticipated declines of the 1990s.

Race-Specific Homicide Offending Trends

Disaggregating total homicide rates by race indicate that the African American homicide rate has been considerably higher than that of whites since 1980. (Note that the African American rate has been divided by five so the variation in the white homicide rate is not dwarfed by the substantially higher minority rate.) Moreover, the white homicide rate has remained relatively more stable, fluctuating between 6.4 (highest rate, 1980) to 3.4 (lowest rate, 2008), compared with African American homicide, which fluctuated from 51 (10.2 in figure after being divided by 5) (highest rate, 1991) to 24.5 (lowest rate, 1999). The significantly steeper growth and decline in African American homicide rates suggests that the crime decline in the 1990s was disproportionately influenced by falling homicide rates among African Americans. Again, although a parsimonious example for why African American homicide rates fell dramatically during the 1990s does not exist, the following section sheds light on possible explanations, all of which contributed in part to this decline. (Figure 3).

Crime Decline: Explanations

The major hypotheses that have been proposed to explain the crime decline of the 1990s are delineated below. First, we discuss the demographic influence of age structure and ethnic immigration. Second, we present the role of criminal justice factors – such as incarceration, police forces and strategies, as well as gun control interventions – which may have contributed to the declining violent crime rates. Finally, we shift to social and economic explanations that have been offered, such as the waning crack-cocaine markets, the economic boom of the 1990s and the impact of legalized abortion that led to the drop in numbers of unwanted births who would have been in their crime-prone ages during the 1990s – about 20 years after the passage of those abortion laws. We conclude with summary discussions of each of these proposed explanations.

Age Structure

Criminologists widely acknowledge the existence of an 'age–crime curve,' or the tendency for individual criminality to peak in adolescence and early adulthood and decline thereafter (Hirschi and Gottfredson, 1983). The pervasiveness of the age–crime curve suggests that a larger proportion of young people in the total population should equate to a larger pool of criminal victims and offenders and thus a higher crime rate more generally. Early articles reported considerable support for this idea (see Sagi and Wellford, 1968), and the youth age structure trend was found to closely mirror the precipitous increase in crime rates of the 1960s and 1970s (besides a dip in 1975) and subsequent decline beginning around 1980 (Cohen and Land, 1987). Therefore, many criminologists explored this demographic force to explain the crime decline of the 1990s.

More recently, Marvell and Moody's (1991) extensive review identifies statistically significant and positive relationships between the relative size of the youth population and crime rates (i.e., homicide and burglary) in almost all studies under consideration. Some scholars suggest that future crime rates can be forecasted on the basis of the projected size and age composition of juvenile and adult populations. For instance, Blumstein et al. (1980) accurately

predicted that crime rates would peak in 1980 as the postwar baby boom birth cohort moved out of high crime ages.

Although the aforementioned studies would suggest that the crime drop of the 1990s had much to do with changes in age structure, some scholars express doubts. Zimring (2007) argues that New York City experienced only a slight reduction in the total number of males in their late teens to late twenties in the mid-1990s, yet also experienced a major crime decline. Others argue that when crime rates were declining in the late 1990s, the number of 15- to 24-year olds in the U.S. population was increasing and continued to do so into the twenty-first century while crime rates continued to decline (Blumstein and Rosenfeld, 1999, 2008; Levitt, 2004). Additionally, the effects of age composition on crime rates can be offset when age compositional changes are slow or when such changes occur along with other demographic changes, such as changes in the relative size of racial minority groups (Blumstein and Rosenfeld, 2008; Levitt, 2004).

Also problematic is that a number of forecasts prior to the crime drop based on age composition projections were largely unsuccessful. Steffensmeier and Harer (1987) predicted significant declines in violent and property crime from 1980 to 2000 and thus unanticipated the crime rise beginning in the mid-1980s. Others predicted that anticipated massive increases in the proportion of youths in the late 1990s would produce a '"crime bomb' and the emergence of young, ultraviolent 'superpredators' after the turn of the century (Dilulio, 1996). However, proponents of the crime storm based their predictions solely on the size of the youth population and did not take into account relative sizes of middle-aged and elderly populations (Steffensmeier and Harer, 1999). Additionally, forecasts are strongly influenced by recent crime trends, which produce projections that are based on expected, not actual age-specific crime rates. Thus, although age composition is certainly an important covariate of crime rates, a large share of youth in the population does not inevitably translate into higher crime rates. In fact, the recent increase in the 15- to 29-year old population from 2000 to 2010 has been accompanied by a leveling and then declining crime trend. Hence, evidence points to other forces that define the crime decline of the 1990s.

Immigration

Conventional wisdom has supported the view that immigration promotes crime (Gurr, 1989). Social disorganization theory suggests that immigration influxes introduce cultural and language differences among community residents, and thus attenuates community bonds and informal controls and in turn enhances social disorder and crime levels (Shaw and McKay, 1969 [1942]). However, violent crime reductions in recent decades have coincided with the influx of foreign-born individuals (Simanski, 2005). Additionally, many U.S. cities with high concentrations of immigrants have relatively low crime rates and experienced some of the largest crime reductions in the 1990s (Martinez and Lee, 2000). A number of studies based on longitudinal and time-series data find that increases in immigration contributed to the crime decline in the 1990s (Ousey and Kubrin, 2009; Stowell et al., 2009; Wadsworth, 2010). Accordingly, it may no longer be justifiable to assume that immigration and diversity are automatic determinants of social disorganization and crime.

A number of explanations have emerged for why higher immigration levels may lead to lower levels of crime. Many scholars point out that immigrants are less likely to engage in criminal behavior than other racial groups; thus, a larger proportion of law-abiding citizens logically equates to a lower overall crime rate (Butcher and Piehl, 1998; Hagan and Palloni, 1998; Sampson and Bean, 2006). Others point out culturally-based protective factors such as marital/family stability, extended family, religiosity, employment networking, and collective efficacy among immigrant enclaves (Ousey and Kubrin, 2009; Sampson et al., 2005; Wadsworth and Kubrin, 2007). Some posit that immigration promotes positive changes in the general character of communities by stimulating the creation of new institutions such as churches and self-help groups (Martinez and Valenzuela, 2006). Logan et al. (1994) argue that low-skilled service markets heavily depend on immigrant labor, and thus reduce unemployment rates in immigrant communities. Finally, some scholars have pointed to a selection effect, which suggests that foreign-born individuals who come to the U.S. are relatively more motivated, talented, and law-abiding than those who do not (Martinez, 2002).

Despite empirical support, some scholars have been skeptical of the crime-reducing potential of immigrant populations. For instance, Skogan (2009) argues that two-thirds of the crime decline in Chicago since 1991 transpired in African American neighborhoods, whereas gang activity and crime increased in Hispanic neighborhoods. Accordingly, Skogan refutes the notion that immigrants exhibit lower levels of criminal behavior, but rather, that undocumented immigrants go to considerable lengths to avoid attention from law enforcement officials. Also, a number of cross-sectional (Reid et al., 2005) and longitudinal studies (Baumer, 2008; Butcher and Piehl, 1998) find that increases in immigration have had a negligible effect on recent crime trends. Finally, some studies find that although first-generation immigrants display lower levels of criminal involvement, criminal behavior is considerably more common among second- and third-generation immigrants (Hagan et al., 2008; Hagan and Palloni, 1999). Despite contradictory findings, there is enough evidence to suggest that growing immigration patterns in some areas contributed to declining crime rates during the 1990s. The immigrant population has continued to grow since the 1990s during a time when the crime trend plateaued until 2006 and subsequently declined.

Moving from demographic factors, many politicians and police chiefs have claimed that criminal justice practices have resulted in curbing crime rates during the crime decline period.

Incarceration

Beginning in the early 1970s, imprisonment rates in the U.S. soared. By the end of the twentieth Century, the incarcerated population had quadrupled with the number imprisoned climbing from 500 000 in 1972 to two million (Spelman, 2000). Incarceration could affect crime rates via incapacitation,

deterrence, or rehabilitation. Distinguishing among these forces has proven to be a difficult if not insurmountable statistical challenge to date (Blumstein et al., 1978). Scholars have long debated the effects of incarceration on crime rates – some arguing that criminal justice sanctions deter criminal offending (Ehrlich, 1973) and others arguing that prisons have a criminogenic effect (Vieraitis et al., 2007). Scholars have established a link between incarceration and crime rates (Levitt, 2004; Stemen, 2007; Zimring and Hawkins, 1973), and incarceration is listed among the major factors credited for declining crime trends of the 1990s (Levitt, 2004). By and large, the weight of evidence supports the dampening effect of incarceration rates on subsequent crime rates (as well as the positive effect of growing crime rates on imprisonment rates). Recent research by Levitt (2004) and Baumer (2008) suggest that imprisonment (the effect of stock and flow, respectively) accounts for a relatively large percentage of the drop in crime rates during the 1990s (estimates ranging from about 10 to 35% of the decline) making incarceration one of the substantial contributors to the crime decline. Studies of the elasticity of incarceration suggest that the increased effectiveness of incarceration in reducing crime rates may be due to the growth in the scale of imprisonment, the proportion of adults represented among those incarcerated and the focused efforts of law enforcement to get the more serious offenders off the street (Spelman, 2000). On the other hand, some scholars provide evidence of the diminishing returns of these rising imprisonment trends that suggests, after a point, growing imprisonment may actually increase crime rates as optimum deterrent and incapacitation effectiveness is surpassed (Liedka et al., 2006). There are growing concerns among scholars that the release of these prisoners (about 500 000 released in 2000) back into their home communities may have deleterious effects on crime trends (Rose and Clear, 1998).

Even though there appears to be a general consensus in the literature about the effect incarceration has had on reducing crime rates during the 1990s (Blumstein and Rosenfeld, 2008), researchers note that the incarceration rate was climbing long before the precipitous decline of the 1990s crime rates (Blumstein and Rosenfeld, 1998). Furthermore, since 2000, the incarcerated population continued to climb until 2009 when the numbers began to drop – the period when the crime trend leveled off, and renewed its decline. Scholars continue their work to hone the precision of statistical techniques used to assess this relationship; and the growing knowledge of the limitations of previously employed model specifications call into question the confidence some scholars have in inferences drawn from the current body of evidence (Spelman, 2008).

Police Force and Policing Strategies

A great deal of credit has been claimed by police commissioners and politicians for the role that the police had on the declining crime trends of the 1990s. Attention not only has been given to changes in the size of the police force but also to changes in the focus of policing efforts and policing strategies. Many police departments shifted from strictly reactive policing as they adopted new innovations in police tactics in the 1980s and 1990s. A myriad of strategies were implemented, including community-oriented policing, problem-solving policing, zero-tolerance policing, and targeting public disorder and weapons carrying. Therefore, the impact of law enforcement is among factors identified in the crime decline literature. Amidst claims of law enforcement's successful efforts in reducing crime, relatively few carefully designed studies have been conducted to test this relationship during the years of the crime decline. Scholars have called into question the influence law enforcement efforts have on curbing crime because the widespread crime decline occurred in many U.S. cities where such tactics had not been introduced (Blumstein and Rosenfeld, 1998). Furthermore, a direct link between policing and crime rates is difficult to determine as many cities' crime rates were already declining by the time policing initiatives were introduced (Eck and Maguire, 2000).

Eck and Maguire (2000) had conducted a thorough review of research on the impact of the number of police personnel on crime and found mixed evidence even after assessing only the more rigorous studies that addressed methodological issues such as simultaneity. Nevertheless, more recent research focusing on the period of the crime decline has produced evidence that the size of the police force (officers on the street) had a dampening, although limited, effect on violent crime rates (Baumer, 2008; Levitt, 2004).

Research examining more targeted police initiatives has provided some support for their contribution to falling crime rates, such as Boston's Operation Ceasefire (Braga et al., 1999), New York City's Compstat (Messner et al., 2007), Richmond's Project Exile (Raphael and Ludwig, 2003), Kansas City's Gun Experiment (Sherman et al., 1995) and St. Louis' Firearm Suppression Program (Rosenfeld and Decker, 1996). Rosenfeld et al., (2005) compared police strategies and their effectiveness in reducing violent crime trends among the programs in Boston, New York City, and Richmond along with a sample of cities that did not implement these police tactics. They found modest support (only for Richmond) that new policing interventions differentiated falling violent crime rates across U.S. cities during the 1990s. The effect of policing on the crime decline warrants further scholarly attention in order to provide definitive evidence about the nature and magnitude of this relationship (National Research Council, 2004). Eck and Maguire (2000) concluded that law enforcement's focused attention on high-crime neighborhoods likely contributed to the reduction in crime rates; and also that overall effectiveness of policing is realized typically as part of a coordinated network of institutions, including formal (e.g., courts and schools) and informal (families and churches) institutions. Other evidence suggests that successful police tactics are those that target specific hot spots and violent offenders (National Research Council, 2005). Another review suggests that the diverse police strategies introduced in the 1990s likely contributed very little to the crime drop (Eck and Maguire, 2000).

The majority of the decline in homicides during the 1990s was accounted for by gun-related homicides (Fagan et al., 1998); therefore, some have given credit to gun control legislation and police strategies that targeted illegal possession of guns and gun-related crimes during this period (Sherman and Rogan, 1995).

Like most studies of police interventions, initiatives toward gun control and the reduction of gun-related violence were seldom evaluated using systematic and multivariate methodological techniques. Most reports are descriptive in nature and only a small percentage of these studies would pass the basic requirements of sound statistical analysis for attributing success to these programs (Wellford, 2005: 674). As stated among the concluding remarks from a critical review of firearms and violence studies published by the National Research Council with regard to place-based policing of firearms and targeted violent gun offenders:

> … in the committee's view, the existing data and methods make it difficult to assess how … policing programs affect crime. Researchers cannot hope to credibly control for the many confounders that influence violence and crime using simple time-series comparisons (National Research Council, 2005: 241)

Although a number of these initiatives were introduced during the 1990s, it is difficult if not impossible to separate the unique effects of these policing and firearm strategies from other concurrent effects on the declining homicide rates without different methodological designs and statistical tests (National Research Council, 2005). Without clear assessments of these programs' effectiveness in reducing crime, it is certainly difficult to determine the extent to which these programs had an impact on reducing crime rates in the 1990s net of the effects of other influences. Some scholars attribute limited significance to interventions such as policing strategies, gun control, and concealed weapons laws on influencing the crime decline (Levitt, 2004).

Aside from criminal justice policies and practices, criminologists have examined the influence of social, economic, and situational forces to explain the crime decline.

The Rise and Fall of the Crack-Cocaine Market

The link between U.S. crack-cocaine markets and violent crime rates is a salient theme in the crime decline debate (Blumstein and Rosenfeld, 1998; Levitt, 2004). Blumstein's (1995) 'crack-cocaine thesis' argues that the intensified demand for crack-cocaine accounts for the substantial increase in homicides and robberies in urban America during the 1980s and early 1990s and that violent crime rates declined with the increase in drug-related arrests and the subsiding crack-cocaine demand in the 1990s. The following section discusses characteristics of the crack-cocaine market that influenced an increase, followed by a subsequent decrease in violent crime.

In an illegal drug market, disputes involving drug transactions, territories, and other matters are unlikely to be mediated by the police or other formal modes of control. Consequently, the growth in the crack-cocaine market is purported to have increased violent crime because it heightened the use of informal and violent forms of conflict resolution. Beyond this, crack-cocaine transactions are likely to transpire between strangers, a characteristic that may heighten feelings of suspicion and lead to a "shoot first and ask questions later" mentality (Ousey and Lee, 2007). More importantly, intensified law enforcement efforts that incarcerated early forerunners of crack markets created a 'replacement effect,' whereby younger and more inexperienced individuals took over control of crack-cocaine markets. Compared with their predecessors, these replacements were more reckless, more likely to carry handguns, and quicker to resort to lethal forms of conflict resolution (Blumstein, 1995). As the crack-cocaine trade became more lucrative, it also became more violent - characteristics that regularized gun-toting not only among those directly involved in trafficking, but also as a means of self-defense among uninvolved individuals who lived in geographical areas deeply implicated in the crack-cocaine trade (Blumstein, 1995).

Some scholars attribute the decline in violent crime in the 1990s to decreasing levels of crack-cocaine market activity following intensified law enforcement efforts in addition to the declining numbers of new users as information regarding the negative consequences of crack-cocaine involvement became widespread (Blumstein and Rosenfeld, 1999). Ousey and Lee (2007) argue that the violent crime decline can be attributed not only to the subsiding of drug markets, but also to the attenuation of the drug market-lethal violence relationship, which had created a "kinder and gentler" drug market than that of the 1980s and early 1990s. Specifically, as marijuana became the drug of choice among young drug users in the 1990s, the crack-using population became increasingly characterized by older, less impulsive, and less violent individuals compared with their younger counterparts during the peak of the "crack era" in the late 1980s (see Johnson et al., 2000). At the same, drug transactions were becoming significantly less likely to transpire in visible street markets, instead moving to private, indoor settings among trusted friends or regular customers (Curtis, 1998).

Several studies indicate that U.S. cities that experienced high levels of crack activity or significant increases in crack use in the 1980s also experienced momentous upsurges in violent crime (Baumer et al., 1998; Messner et al., 2005; Messner et al., 2007). However, other studies find less definitive support. Kelling and Sousa (2001) find that the declining use of crack cocaine, as represented by the number of hospital discharges for cocaine-related incidents, is not associated with the decline in violence in New York City. Corman and Mocan (2000) employ a time-series analysis of crime and drug use in New York City, and report that murder and assault rates are not related to changes in the rate of drug use. The authors speculate that the significant increase in the supply of crack cocaine during the 1980s created cocaine surpluses among drug dealers, and thus reduced violent interactions that were once again prevalent among drug dealers due to a more limited supply of available cocaine.

Economic Growth

Improving economic conditions during the 1990s have been proposed to account for the declining crime rates during that decade. Criminologists have theorized the link between economic conditions and crime rates arguing that offenders are motivated by economic strain (Merton, 1938) and/or that routine activities facilitate opportunities for crime during economic upswings (Cohen et al., 1980). Typically using

unemployment rates as their economic indicator, criminologists have generated mixed support for the relationship between economic conditions and crime rates (Chiricos, 1987; see Cantor and Land, 1985 for countervailing forces explaining these mixed findings). Some individuals who lack lucrative, legitimate employment opportunities (especially youth and minorities) may turn to illegitimate opportunities for economic gain when those illicit opportunities present themselves as was the case in many inner cities during the crack-cocaine epidemic of the mid-1980s extending to early 1990s (Freeman, 1996).

Between 1991 and 2001, gross domestic product (GDP) per capita increased by 30% in the U.S.; and not only did the unemployment rate drop from 6.8 to 4.8%, but real wages increased and legitimate labor market opportunities improved. Even though many of these job opportunities were low-wage, unskilled positions, they provided many youth with a safer work environment than what the illegal drug market had afforded them during the heyday of the crack-cocaine market (Blumstein and Rosenfeld, 1998). Yet, empirical support found for the relationship between economic expansion of the 1990s and the declining crime rate has been modest and applies primarily to property crimes and robbery. Researchers examining this relationship have operationalized economic forces using measures such as the unemployment rate (Gould et al., 2002), business cycles (Arvanites and Defina, 2006), and real wages (Gould et al., 2002). There is essentially no systematic support for the effect of improved economic conditions and the declining homicide trends of the 1990s. Levitt (2004) argues that the economy does not have a direct impact on crime rates but may work largely through increased resources available to criminal justice agencies (police and prisons) during these times of economic upswings. This may account for the fact that the economic crises of the twenty-first century have not been accompanied by rising crime rates, but instead with a flattened trend through 2006 followed by another crime decline.

Another indicator of economic health, consumer sentiment, has been proposed as a better predictor of crime trends because it captures the subjective aspects of economic conditions. Rosenfeld and Fornango (2007) find robust evidence for the effect of their consumer sentiment summary index on property crime and robbery trends. Although their study does not test the association between consumer sentiment and homicide trends, Blumstein and Rosenfeld (2008) argue that the close parallel between homicide and detrended consumer sentiment index trends and, likewise, the similarity between the robbery and homicide trends during the last few decades of the twentieth century suggest there may exist a link between economic conditions and homicide trends using this index of consumer sentiment. Although there appears to be consistent empirical evidence for a modest influence of economic forces on property crime and robbery trends, as yet there is no support for its impact on other violent crime trends.

Legalized Abortion

One of the most contentious explanations for the crime drop is Donohue and Levitt's (2001) "abortion dividend" thesis, which attributes up to half of the crime decline in the 1990s to the legalization of abortion in the early 1970s. The authors argue that changes in abortion laws produced smaller cohorts of teenagers and young adults in the 1990s in addition to fewer numbers of unwanted children who would have been born to high-risk mothers (i.e., young, unmarried, low educational attainment and economic status) and in high-risk birth conditions (i.e., low birth weight, prenatal exposure to drugs and alcohol, neurological deficits) (Levitt, 2004). To support their claim, Donohue and Levitt argue that states that legalized abortion before the 1973 *Roe vs Wade* decision experienced crime declines earlier than other states, and states with higher abortion rates in the 1970s saw the most significant crime declines in the 1990s. Other studies also find that abortion laws contributed to crime declines in recent decades, although most find its effect to be much lower in magnitude than was estimated by Donohue and Levitt (Baumer, 2008; Berk et al., 2003).

The abortion-dividend thesis has also attracted a great deal of skepticism. Many scholars note that the timing of abortion laws and the crime decline in the 1990s were temporally out-of-synch (Rosenfeld, 2004). Specifically, they argue that crime declines occurred several years later than they should have based on the timing of abortion law implementation and also that increases in violent crime in the early 1990s were greatest among African Americans adolescents, although African American women were more likely to have abortions than other racial groups (Blumstein and Wallman, 2006). Also, Zimring (2007) points out that Canada did not remove restrictions on abortion until 1989, yet experienced significant crime reductions at the same time that the U.S. did. Others claim that the abortion-crime link is not causal, but rather is confounded with the rise and fall of crack markets (Blumstein and Wallman, 2006). For instance, Cork (1999) argues that even though states that legalized abortion earlier than 1973 (e.g., New York and California) did experience earlier starts to the crime drop; this was because these states underwent the rise and fall of the crack epidemic earlier than other states.

Conclusion

The major hypotheses that have been proposed to explain the crime decline of the 1990s are varied and some have generated considerable debate among scholars. The demographic factors including age structure likely have little direct bearing on the decline; and immigration trends may have contributed to some of the decline, but research suggests countervailing forces related to immigration may limit the extent to which these patterns accounted for the decline. Criminal justice policies – that led to unprecedented proportions of the population being incarcerated and to innovative policing strategies and gun control interventions – have been shown to contribute to the declining violent crime rates – in particular, incarceration trends. Unfortunately, limitations in research design of policing and gun control tactics leaves out the extent to which these factors curbed crime rates in question. The diminishing crack-cocaine markets may be linked to the crime decline although the widespread handgun availability that seemed interrelated with drug market activity showed no

sign of fading. The economic growth of the 1990s provided legitimate labor market opportunities to many youth who, in prior years, were attracted to the lucrative, though dangerous, illicit drug trade; yet research showed that economic forces impacted declining property and robbery crime trends rather than other personal crime trends such as homicide. The impact of legalized abortion was one of the explanations for the crime decline that generated lively scholarly debates in the literature, and some support emerged that it may have accounted for some of the crime decline – indirectly, if not directly. No one of these explanations by itself can account for the crime decline; but likely in combination – and some of which interacting – they all contributed to some extent. A body of literature accounting for crime trends since the turn of the twenty-first century has yet to emerge, but we can expect to revisit many of these social and economic forces when scholars attribute their influence to account for recent fluctuations.

Crime: Whitecollar

Susan P Shapiro, American Bar Foundation, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The term 'white-collar crime' was coined by criminologist Edwin H. Sutherland, who argued that, because the offenses of corporations and white-collar workers are not represented in official crime statistics, scholars misunderstand the nature, causes, and consequences of crime and its control. This article describes how some of the standard topics in criminology – the social organization of offending, victimization, enforcement, prosecution, punishment, and criminological theory – are transformed when one looks in the unconventional places captured by the varied conceptions of white-collar crime. The article also considers the methodological and normative impediments to the study of crime and justice in the suites.

The term 'white-collar crime' was coined by Edwin H. Sutherland, in a 1939 presidential address to the American Sociological Society, as "crime committed by a person of respectability and high social status in the course of his occupation" (Sutherland, 1940, 1949, p. 9). In the better part of the century that followed, scholars continued to disagree about this definition of the concept – from its focus, not on illicit acts, but on specific characteristics of individual lawbreakers, to its characterization of their misdeeds as 'crimes.' Although more eschewed than embraced his early definition, Sutherland's compelling label persists. But a vast collection of synonyms giving linguistic expression to conceptual, theoretical, and ideological differences proliferated – upperworld, elite, suite, of-the-powerful, corporate, organizational, occupational, employee, avocational, trust, business, economic, official, governmental, or political crimes, illegalities, offenses, violations, deviance, misconduct, harms, or violence. After decades of fruitless conceptual debate, most scholars have agreed to disagree.

This babel of competing verbiage and the disparate phenomena it embraces would be a mere annoyance were it not for the fact that the term was born, as Robert Merton once observed (Merton, 1957, pp. 90–92), of an effort to 'liberate' scholarship from 'cognitive misbehavior' reflected in the well-accepted but spurious correlation between poverty and crime. Concepts tell us where to look, and where we look, affects what we find. Sutherland asserted that criminologists, obstructed by conceptual blinders, had been looking in the wrong places:

> …[white-collar crimes] are not included in the criminal statistics nor are individual cases brought to the attention of the scholars who write the theories of criminal behavior. The sample of criminal behavior on which the theories are founded is biased as to socio-economic status, since it excludes these business and professional men. This bias is quite as certain as it would be if the scholars selected only red-haired criminals for study and reached the conclusion that redness of hair was the cause of crime. (Sutherland, 1949, pp. 8–9)

In other words, if scholars look only at crimes committed by the poor, it is not surprising that they conclude that poverty and its associated pathologies cause crime. For Sutherland, this selection bias is the *raison d'être* of inquiry into white-collar crime. These offenses evoke that nagging sense of all that is ignored by traditional criminology and that cause us to misunderstand the nature, causes, and consequences of crime and its control.

In the ensuing years, white-collar crime has become a subject of inquiry in its own right, of course. But selection bias continues to symbolize the essence of white-collar crime scholarship, simultaneously signaling its promise and foreshadowing its vulnerability, accounting for why the work is provocative and groundbreaking, and yet so often misguided. This article explores this dual tension, thereby featuring a handful of the major contributions of this scholarship and the challenges that social scientists face in doing it well.

Removing the Blinders

We begin by considering how some of the standard topics in criminology are transformed when one looks in the unconventional places captured by the varied conceptions of white-collar crime.

The Social Organization of Offending

Although Sutherland's early definition explicitly referred to individuals, his empirical work (Sutherland, 1949) on the offenses of the 70 largest manufacturing, mining, and mercantile corporations in the United States took organizations as the unit of analysis, a legacy reflected in the generations of scholars he spawned. Although organizations surely commit misdeeds, they cannot do so without the complicity of individuals, often countless individuals plucked from disparate branches of the corporate tree and from tiers spanning the organizational hierarchy, indeed individuals often situated outside of the organization altogether – lawyers, accountants, investment bankers, brokers, agents, consultants, advertisers, competitors, even regulators. But coordinating the activities of such a diverse collection of collaborators situated across the globe, many of them ignorant of the illicit activities to which they contribute and often engaged in concerted action spanning years or decades, is not easy. Organizations need to maintain secrecy, lest the activities be exposed. They must ensure that some conspirators remain unwitting of the consequences of their

actions, lest they refuse to participate or blow the whistle to regulators inside or outside the organization. They must maintain loyalty and commitment and cool out those with little taste for offending, lest disgruntled or disaffected conspirators sell out their colleagues. They must buffer those in positions of power from those carrying out their directives to shield the former from accusations of culpability or to build a paper trail that deflects responsibility away from those most complicit. They must deceive and cover up their activities from victims to ensure their continued victimization and to postpone discovery. They must destroy or doctor evidence to subvert regulatory discovery and to undermine the prosecution of their misdeeds, if discovered. These are massive organizational tasks perhaps better suited to the theoretical paradigms emanating from organizational sociology than from traditional criminology and that provoke unique challenges for systems of social control (Stone, 1975).

Victimization

White-collar crimes exploit impersonal trust, asymmetric relationships in which principals entrust strangers to provide specialization, intermediation, and collectivization (Shapiro, 1990). Victims of white-collar crime, therefore, typically lack expertise and access to the information necessary to evaluate the conduct of trustees. Because many participate in 'futures transactions' such as investment and insurance where payoff is delayed or protracted, victims have no tangible data in the interim to assess the likelihood that commitments will eventually be honored. Victims of white-collar crimes, therefore, tend to be unwitting. Because victims of common crimes are readily aware that they have been robbed, burglarized, assaulted, or victims of larceny, and members of their social networks know when associates have been killed, systems of social control (and researchers as well) tend to be reactive. They wait for victims to tell them that a crime has occurred. Reactive systems of social control yield little, stale, and biased data (about more blatant misdeeds) when most victims are unwitting. The policing (and study) of white-collar crime therefore requires different methods than those characteristic of common crimes.

White-collar offenses also differ from common crimes in the recruitment, pattern, scale, and impact of victimization, and in the relationships between victims and offenders. Because some relationships of trust collectivize the interests of multiple principals – in financial institutions, mutual and pension funds, insurance pools, and the like – victimization from the abuse of trust is often massive. Moreover, because white-collar crimes tend to be delivered by organizations whose activities touch countless consumers, clients, employees, investors, and neighbors (who drink the water and breathe the air poisoned by the corporation), victimization is often extensive and its cost enormous. Research finds that the organizational complexity of an offense is "the single most powerful predictor of victimization" (Weisburd et al., 1991, p. 93). Hence, the organization itself becomes the 'weapon' in white-collar crime. It is "for white-collar criminals what the gun or knife is for the common criminal – a tool to obtain money from victims" (Wheeler and Rothman, 1982, p. 1406).

Enforcement

Systems of social control can be differentiated into those which seek 'compliance' – preventing the occurrence of law violations – or 'deterrence' – reacting to violations that have already occurred (Reiss, 1984). Because white-collar offenses portend significant victimization with respect to cost, harm, consequences, irreversibility, and numbers of victims, enforcement systems frequently opt for compliance over deterrence. Regulators would rather prevent toxic waste or abort a securities swindle than punish those responsible, especially when the unwittingness of victims often means that significant harm has been done by the time reactive deterrence systems learn of the illegality. And many find that cooperative enforcement techniques are better able to secure compliance than those structured to deliver punishments (e.g., Grabosky and Braithwaite, 1986).

Compliance systems are more common in the enforcement of white-collar than common crimes as well because the former are more predictable. Because would-be organizational offenders are relatively stable and visible, as they seek to market their wares, they can be licensed, given preclearance, inspected, monitored, and subject to regulations and mandated procedures.

The policing of white-collar crime is also more diversified than that of common crime, which is undertaken largely by the state and private police (e.g., security guards). The costs and consequences of white-collar crimes, the penalties imposed, and the loss of reputation and the diminution of institutional trust (which are the lubricants of continued business) are so great that those likely to bear these costs often undertake their own social control. Insurers, stock and commodity exchanges, professional or trade associations, and organizations themselves undertake or mandate self-regulation or buy the regulatory services of outside auditors, inspectors, rating firms, and the like.

Prosecution and Punishment

Scholars object, with good reason, to Sutherland's classification of white-collar offenses as 'crimes.' Many – perhaps most – so-called white-collar crimes are, in fact, not prosecuted as crimes at all or subject to criminal penalties. Compliance systems of social control have little use for the criminal justice system (aside from the incentive that potential criminal penalties give for undertaking self-regulation or abstinence). Criminal sanctions come too late, after the damage is done; they require standards of proof that are difficult to meet, especially with extensive obfuscation and cover-up that shield those most complicit; they do little to remedy the harm, lessen its impact, or impede future wrongdoing. Moreover, the choice between imprisonment and relatively small criminal fines offers limited options when the criminals are wealthy organizations. White-collar offenses are often dealt with by civil injunctions or administrative remedies that are better able to abort incipient or ongoing violations, contain the damage quickly, remedy the harm, provide restitution to victims, and fashion remedial solutions that will reduce opportunities for future wrongdoing without exacerbating the harm to innocent parties. Moreover, because wayward organizations or their insurers often have

deep pockets, victims and the private plaintiff's bar have strong incentives to undertake civil litigation against white-collar malefactors. Private litigation often plays a significant role in rectifying the misdeeds, securing compensation, meting out punishment, and deterring future misconduct.

Criminological Theory

As even these few selected features of white-collar crime scholarship make clear, Sutherland's *raison d'être* for drawing attention to these offenses was prescient. By broadening the expanse of crime and its control from those patterns and institutions evoked by the stuff of traditional crime statistics to those insinuated in organizational offending and abuse of trust, the limitations of criminological theory are readily exposed. The challenge of incorporating into criminological theory the phenomena observed once the conceptual blinders were removed has been less successful.

Over the years, there have been sporadic attempts to develop a general theory of crime that accounts for both white-collar and common crimes. Sutherland's theory of differential association – that the techniques and motivations for criminal behavior are learned through contact with others – represents the earliest attempt (Sutherland, 1949, p. 234). Some scholars have extended Merton's anomie theory of deviance or variants of strain theory, proposing that, like ordinary deviance, white-collar crimes arise when legitimate means to achieve material success or to attain organizational goals are blocked or unavailable. And other theories of white-collar lawbreaking have drawn on and refined rational choice, self-control, neutralization, conflict, and especially variations on opportunity theories (Benson and Simpson, 2009; Shover and Hochstetler, 2006), all originally used to account for traditional crimes.

These varied theoretical paradigms have been subject to extensive and justifiable criticism for imprecision, tautological reasoning, inability to account for compliance and law-abiding behavior, confusing correlation and cause, or lack of empirical support. While some scholars continue to refine grand theories of white-collar and common crimes, others eschew such theories, developing explanations for specific misdeeds or those that account for variation within particular datasets.

Methodological Pitfalls

The empirical challenges to the study of white-collar crime far outweigh the theoretical ones. First, because of victim unwittingness, relationships of impersonal trust, the protection of crime in the suites by institutions of privacy, complex cover-up schemes, the commission of crime with organizational weapons rather than physical ones, and the ability to buffer misdeeds in long-latent futures transactions, the dark figure of undetected white-collar crime probably exceeds that of all other crimes combined. And even where law enforcement officials have discovered white-collar offenses, they are often unable to ascertain or pin the blame on those most responsible. The most common sources of data on traditional crimes – arrest records and crime statistics, victimization surveys, and observation studies – therefore yield little and very biased data on white-collar crime.

With limited access to data, researchers often rely on materials in the public domain – typically, sentencing data, reports of administrative agencies, journalistic accounts, hearings, and official inquiries. But selection bias is the price of easy access. Journalists produce what sells – the egregious, scandalous, shocking, clever, costly, and devastating offenses committed by notorious or colorful characters, where those in high stations fell from grace, where safety nets failed, where victims should have known better, where offenders received excessively lenient treatment – many of the same features of offenses that incite public hearings and legislative inquiry. Hardly the mundane stuff of white-collar crime day in and day out. In selecting research subjects from the news media and political tribunals, scholars replicate Sutherland's red-haired crime fallacy. We come to believe that these crimes are committed (with impunity) by the rich and powerful, when a less biased data source would reveal that they are typically carried out by members of the middle class, and that, contrary to expectation, the severity of punishment of white-collar criminals appears to increase with social standing (Weisburd et al., 1991).

Turning to public records of convicted criminals incurs other selection biases. Convictions represent a very small and unrepresentative tip of the iceberg. Research on the US Securities and Exchange Commission, for example, indicates that not even 5 of every 100 parties found after investigation to have violated the securities laws are convicted of a crime (Shapiro, 1984; pp. 155–161). Criminal courts are less likely to process the misdeeds of organizations (than of individuals), that were uncovered by compliance (rather than deterrence) systems of social control, and that were committed by those atop corporate hierarchies who were able to conceal their responsibility or inculpate others in exchange for immunity from criminal prosecution. When offenses are ongoing, victimization is extensive, and the impact is significant, law enforcers opt for compliance – halting the misdeeds, forestalling, and remedying the harm, minimizing the likelihood of recurrence, and doing so with more immediacy, less litigation, and lower standards of proof – over criminal proceedings. Therefore, although serious significant offenses can certainly be found at the tip of the iceberg, so can some of the most trivial for which no remedy other than criminal prosecution is available. Researchers concentrate on the tip of the iceberg at their peril.

Because of these biases embedded in the social construction of white-collar offenses as 'crimes,' many scholars choose not to concentrate solely on criminal cases. Some study offenses that carry criminal penalties, even if they have been resolved instead by private settlements, warnings, injunctions, civil or administrative proceedings, lawsuits, or other remedies. But a slippery slope looms below the tip of the iceberg. As the labels shift from 'crimes' to 'violations,' 'offenses,' 'misconduct,' 'harms,' 'wrongs,' 'deviance,' 'violence,' and so on, the literature becomes cluttered with studies of torts, liability, malpractice, accidents, mistakes, or inadvertence committed by corporations or those in high-status occupations. We dilute white-collar crimes with all manner of misfortune. To include these harms among crimes in the suites is like including fender benders in an ice storm among crimes in the streets.

Sadly, the ideological passions that animated Sutherland's work and that of many of his intellectual progeny, which

cause us to be suspicious of corporations and individuals of wealth, status, and power, also cause us to get sloppy. They permit us to confuse mistake or accident with intentional noncompliance. They lead us to believe what comports with our assumptions, relying on the thin anecdotal data that are readily available rather than probing deeper, using published reports and secondary data rather than collecting primary materials and triangulating data sources. They blind us from questioning and making problematic what seems intuitively true. As a result, we are destined to learn that some of the classic and repeatedly cited 'landmark narratives' of corporate crime – for example, the Ford Pinto affair and the Challenger disaster – actually got the story wrong, confusing misconduct with mistake, and venality and amoral calculation with banal normalized organizational routines (Lee and Ermann, 1999; Vaughan, 1996).

We are also learning what it takes to get the story of long-running technologically, financially, and organizationally complex potential white-collar crimes right. In the case of the Challenger disaster, it took 10 years of persistent, painstaking, methodical research that probed the entire decade that preceded the shuttle explosion that cold January morning; systematic analysis of more than 122 000 pages of documents, 2500 pages of hearing transcripts, and 9000 pages of depositions; dozens of new interviews and site visits; the commitment to learn technical science and engineering; and the willingness of a publisher to print an affordable 600-page scholarly book with almost 100 pages of technical charts, diagrams, memos, and thousands of footnotes to transform a seductive but erroneous account of organizational misconduct into a creditable one of the normalization of deviance and the sociology of mistake (Vaughan, 1996). Vaughan's chronicle, with the conventional (erroneous) account in boldface type juxtaposed against the fuller complex documentary and ethnographic narrative, starkly demonstrates what is at stake in the social construction of white-collar crime scholarship and what is required of future scholars.

The Future of White-Collar Crime

White-collar crimes are dynamic, continually responding to changing features of trust relationships, structures of opportunity for abuse, and strategies of social control. But unprecedented transformations in each of these factors portend major changes in the future course of white-collar crime and its control.

First, relationships of trust are increasingly asymmetric, enlarging opportunities for abuse at the same time that they better conceal misdeeds from victims and social control organizations. On the one hand, social and especially economic interactions are increasingly enacted in virtual space among anonymous parties in often one-shot exchanges. On the other, the objects of exchange have become more complex, abstract, and opaque. For example, mortgages backed by real property are securitized and combined with other pools of securitized assets and then offloaded to countless investors. These securities are then repackaged, sliced, and diced into still other instruments. Others are transformed into derivatives, bets, or other synthetic securities. The most risky slices (or 'tranches') of these instruments are diversified and combined into yet other instruments, now magically stripped of risk. The owners of shares of these varied pools of abstract wealth do not know what they own, how risky it is, or even that they may own the same thing several times over in different incarnations or are even betting against themselves.

Second, the economic landscape is increasingly globalized. Complex, abstract financial instruments are marketed, bought, and sold throughout the world, often over virtual marketplaces. Capital is highly mobile; individual and organizational victims worldwide gravitate to more secure currencies and higher rates of return in other jurisdictions. Corporations and the lawyers, accountants, and other professionals who facilitate their misdeeds are increasingly multinational. Global financial institutions are interdependent. Globalization increases the opportunities to conceal or cover up misdeeds from unwitting facilitators of white-collar crime, victims, and oversight organizations alike. It also creates opportunities for wrongdoers to situate their activities in jurisdictions with more favorable laws or less regulation. Because multinational criminal justice or regulatory organizations (both public and private) are less developed, resourced, and coordinated than their domestic counterparts, globalized misdeeds more easily escape detection or meaningful sanctions. And, of course, white-collar crimes that cross the globe often leave even more victimization and loss in their wake. Great challenges in the social control of white-collar crime therefore lie ahead for scholars to investigate.

White-Collar Crime and the New Social Science

> … societies have been undergoing an organizational revolution. Just as the forests and fields of the physical environment are being replaced by streets and skyscrapers, the primordial institutions around which societies have developed are being replaced by purposively constructed social organization. (Coleman, 1990, p. xv)

Perhaps nowhere has James S. Coleman's influential call for a new social science attuned to the transformation of social life occasioned by the displacement of natural persons by 'purposive corporate actors' been better realized than in the study of white-collar crime. White-collar crime scholarship does not hold a monopoly on the study of organizational offending, of course. Even traditional criminology (which concentrates on the natural persons who populate the primordial social organization which Coleman argues is 'withering' away) has produced the occasional study of gangs, organized crime, terrorism, the distribution of illicit goods (e.g., drugs, gambling) and services (e.g., prostitution, fencing), and the like. But white-collar crime scholarship more than any other area of criminological inquiry has made problematic the difficulties of regulating organizational life and insuring norm compliance within organizational contexts. White-collar crime offers a bridge to the new social science and a compelling window onto the changing structure of social life. As we gaze through the window, we realize the myopia our blinders have imposed.

Criminal Justice and Social Work Practice

Roger Smith, Durham University, Durham, UK

Abstract

This article offers an overview of the complex and conflictual relationship between the ideas and values underpinning social work and those informing the operation of the criminal justice system. It describes the ways in which these tensions have been played out historically, before offering a typology, which seeks to account for the different approaches taken to social work practice with people in conflict with the law. The article considers the role of social work in challenging discrimination endemic to the justice system before briefly considering how to understand 'what works.' In concluding, the article asserts the legitimacy of the social work project in the context of the criminal justice system and restates the importance of retaining a commitment to core professional values, rather than becoming subsumed by the alternative logics of control and punishment. The material here is largely based on experience in the United Kingdom, supplemented with international examples where possible.

Conceptual Challenges and Practice Dilemmas

The juxtaposition of social work and the criminal justice system undoubtedly poses a range of fundamental conceptual and practical challenges. In essence, these relate to the tensions arising from different ways of thinking about and classifying human characteristics and human behavior. It is important, therefore, to start with a brief outline of these inherent tensions, before going on to develop a more detailed understanding of the challenges and possibilities manifesting themselves in the context of social work practice in this field.

At the risk of oversimplification, the criminal process is fundamentally concerned with problematic behavior, holding its perpetrators to account, and imposing measures of control and sanctions proportionate to the identified transgression. Social work, on the other hand, is interested in addressing the problems experienced by those affected by inequality and oppression, and resolving these based on their needs and aspirations. It is likely, therefore, to have a central role in enabling, empowering, and advocating for those who are 'victimized,' particularly those who experience abuse or exploitation, as much as it also has a role in addressing the welfare needs and rights of those who are identified and treated as offenders by the justice system. The place of social work within criminal justice is therefore, for this and other reasons, fundamentally ambiguous.

In addition, social work is not solely concerned with the attributes and actions of individuals, but sees the person in his or her context, and equally acknowledges that the focal point for change is as much social as it is personal. The individual is not the sole focus for intervention and change, and at this basic level there appears to be a significant mismatch between the ambit and activities of the justice system and the objectives and practices of social work.

In the following account, the ways in which these tensions have played themselves out will be explored. This will lead to a consideration of differing modes of accommodation between the two, which enable social work practice to gain some purchase in the criminal justice arena, while remaining true to its underlying professional principles and core values.

The Origins and Development of Social Work with Offenders

It was during the nineteenth century that professional social work (as it is now known) began to gain a recognized place in the criminal justice system. This coincided with the wider emergence of movements directed at meeting the welfare needs of people in difficult and oppressive settings, particularly experiencing the forms of poverty associated with rapid economic change and the formation of modern capitalist societies. In the sphere of criminal justice, the issue of welfare need was closely bound up with the wider emerging distinction between the 'deserving' and 'undeserving' poor. The category to which those in need were assigned had a significant impact on the kind of services to be provided for them, and irrespective of whether or not they had committed a criminal offense, whether they would be punished or helped. Criminalization, however, tipped the balance sharply toward a punitive form of intervention. Gradually, however, as in other areas of welfare practice, such as the treatment of mental ill health, distinctions began to emerge. Certain groups came to be viewed effectively as less than fully responsible for their behavior, simply by reason of their status, and would thus merit by way of intervention something other than simple punishment. Their delinquent behavior might be attributable to their circumstances, or certain characteristics that resulted in diminished responsibility, and so other forms of intervention could legitimately be brought into play to take these factors into account. If they were not, the effects of punishment alone might be to confirm, rather than prevent, a life of crime.

> The want of employment – the prevalence of improvident marriages – the degrading tendencies of the poor laws – and the increased facilities for the consumption of spirituous liquors have doubtless contributed much to weaken the natural affections of the lower classes of society… Dreadful is the situation of the young offender: he becomes the victim of circumstances over which he has no control. The laws of the country operate not to constrain but to punish him… If when apprehended, he has not attained the full measure of guilt, the nature of his confinement is almost sure to complete it; and discharged, as he frequently is, penniless, without friends, character or employment, he is driven for a subsistence to the renewal of depredations. (Source: Report of the Committee into Juvenile Delinquency, London, 1816 quoted in Muncie, 2009: p. 53.)

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28020-3

For children, the mitigating factors identified might be associated with the circumstances of their upbringing, that is, the effects of parental irresponsibility and wider influences such as mass unemployment, none of which were under their control. Increasingly, too, age alone was seen as a factor that lessened children's level of independent responsibility. For other groups to be seen similarly as acting under diminished responsibility, specific conditions would need to apply, such as mental ill health, or what would now be known as learning disabilities. In some cases, too, those with alcohol problems, or extreme personal circumstances, might also be held as less than fully responsible for any criminal actions they might commit. It was partly because these circumstances or characteristics might not always be clear cut that some of the subsequent machinery for assessing and classifying offenders (welfare reports) began to be developed. In the United Kingdom, for example, the emergence of principles of 'rehabilitation' and 'treatment' of offenders affected by neglect and destitution (especially young offenders) is associated with the introduction of the Probation Act 1907 and the Children Act 1908, which "was notable for its attempt to reconcile welfare and justice imperatives through the establishment of the 'juvenile court' with both civil jurisdiction over the 'needy' child and criminal jurisdiction over the offending child" (Hendrick, 2006: p. 8).

It was in this way that space began to open up for welfare as both a legitimate form of discourse and as a vehicle for the provision of help and support to identified offenders. While from a social work perspective welfare interventions to resolve the problems of those in need are inherently justifiable, from a criminal justice perspective their justification is that they will contribute to reducing or eliminating the prospect of further offending behavior by the individual concerned. It is in this way that a kind of accommodation between the competing discourses of welfare and justice began to emerge. Nonetheless, this rapprochement of ideas was neither clear cut nor stable, and has been the subject of continual renegotiation and contestation subsequently.

Early forms of social work with offenders emerged in the form of targeted services, typically offered by philanthropic organizations, which in turn had strong roots in religious movements. Police court missionaries, for example, took the language of salvation into their practice, as they began to offer advice and support to those identified as offenders in and around the magistrates' courts, seeking to identify those with particular needs and then seeking authority to address these needs in place of punitive sanctions.

1876: Hertfordshire printer Frederic Rainer, a volunteer with the Church of England Temperance Society (CETS), writes to the society of his concern about the lack of help for those who come before the courts. He sends a donation of five shillings (25p) towards a fund for practical rescue work in the police courts. The CETS responds by appointing two "missionaries" to Southwark court with the initial aim of "reclaiming drunkards". This forms the basis of the London Police Courts Mission (LPCM), whose missionaries worked with magistrates to develop a system of releasing offenders on the condition that they kept in touch with the missionary and accepted guidance. (*The Guardian*, 2 May 2007)

Institutionalizing Social Work in Criminal Justice

From the early philanthropic initiatives, there subsequently developed a much more formalized approach to social work provision in the justice system, with the establishment and subsequent expansion of statutory agencies to take on this role. Probation services have progressively been established around the world, with the remit to 'advise, assist, and befriend' offenders where they may have welfare needs. A special issue of the *Probation Journal* in 2011, for example, highlighted developments in countries as diverse as South Korea, France, Russia, Australia, and Japan, indicating that the 'space' for a welfare approach to offending behavior can be achieved across a wide range of cultural variations. On the other hand, it is also acknowledged at the same time that more recent developments, oriented toward risk and behavior management, surveillance, and corrections, have influenced practice across national borders, and there appears to be a widespread trend toward the diminution of the social work role in probation, as in France, for example (Herzog-Evans, 2011).

Over time, too, there has emerged a clear distinction between social work with adult offenders and with children and young people in trouble. This mirrors the distinction between adult and children's jurisdictions and the effective establishment of children as a special interest group by way of international conventions, including the United Nations (UN) Convention on the Rights of the Child, on their rights and just treatment. In effect, with the institutionalization of such measures, children in the justice system do not, as adults do, have to justify their entitlement to special consideration and the prioritization of their welfare interests, since they are *de facto* assumed to be entitled to support and assistance, in principle, at least. In practical terms, this has led to the establishment of entirely separate systems and processes for dealing with young people who get into trouble with the law, including separate jurisdictional procedures and courts, and distinctive institutional arrangements for addressing their welfare needs, such as those afforded by child welfare services.

Consistent with the international principles and objectives articulated under the aegis of the UN, that organization has also taken an active role in promoting and sharing evidence of best practice in 'juvenile justice' with the aim of ensuring that there is a general commitment to the embedding of welfare interventions at the heart of the justice process.

In the area of **juvenile justice**, UNICEF aims to reduce incarceration while protecting children from violence, abuse and exploitation. It promotes rehabilitation that involves families and communities as a safer, more appropriate and effective approach than punitive measures. Justice systems designed for adults often lack the capacity to adequately address these issues and are more likely to harm than improve a child's chances for reintegration into society. For all these reasons, UNICEF strongly advocates **diversion** (directing children away from judicial proceedings and towards community solutions), **restorative justice** (promoting reconciliation, restitution and responsibility through the involvement of the child, family members, victims and communities), and **alternatives to custodial sentencing** (counselling, probation and community service). (UNICEF Child Protection Information Sheet, 2006)

A Typology of Social Work in Criminal Justice

Despite the aspirations of the UN and others to embed effective welfare practice in the justice system, social work continues to sit in an ambiguous position under the shadow of the logic and practices of criminal justice processes, as the precarious position of welfare in probation services appears to underline. There is no doubt that social work practice in criminal justice has been infused with and modified by the logic and rationale of criminalization and the principles of individual accountability. Social work, therefore, often appears to encompass a dual mandate, with welfare intervention predicated on its capacity not just to improve the lives of children and young people, but also to prevent them reoffending, in their own interests. Once this logical leap is made, it becomes practicable and acceptable to incorporate measures of control and correction into 'social work' practice. Despite this elision, and the occasional explicit argument that welfare and justice objectives are coterminous, it remains difficult to sustain the argument that they can be fully aligned in practice, or that this does not simply lead to the co-option of social work in the service of justice-based objectives, in terms of containment and control.

Instead, it is suggested, practitioners should focus first and fundamentally on the values and purposes of social work to develop a typology of appropriate and genuinely enabling forms of practice within the justice system. In certain circumstances, it is likely that these forms of intervention will also support wider aims, such as the prevention of reoffending, but in social work terms these are subsidiary and not principal objectives. We may, for instance, be able to articulate a typology of criminal justice-based social work as follows: resettlement, rehabilitation, socialization, and, emerging more recently, restoration and reconciliation. It has also suggested that social work could and should adopt a 'welfare rights' approach to working in the justice system, although this is more evident as a statement of principle than an established form of practice (see Scraton and Haydon, 2002).

Resettlement

Since the early days of its involvement in criminal justice, social work has been centrally involved in the process of supporting exoffenders to resettle, particularly on release from custodial or other secure institutions. Given that reoffending rates of those released from custody are often very high, and that is linked with a lack of security, it seems that the role of social work in this context is particularly important. Not only does it offer the possibility of supporting exoffenders through difficult transitions, but it may also contribute to reducing the likelihood of further involvement with the justice system.

Resettlement has been established as a central aim of social work intervention with exoffenders for a considerable length of time. As Maguire and Raynor state "the main focus of attention has understandably been on the pressing practical problems faced by many ex-prisoners, and interventions have been driven as much by the charitable aim of helping people in need, as by criminal justice goals" (2006: p. 20). Organizations such as Discharged Prisoners' Aid Societies, originating in the nineteenth and early twentieth centuries in Western societies provided an early stimulus for this kind of social work intervention, which was subsequently built upon and developed by both statutory probation services and organizations such as the UK-based National Association for the Care and Resettlement of Offenders.

This emphasis on aftercare and the provision of effective practical help for those passing through the justice system has continued to form a key element of service provision internationally. In Kenya, for example, the Probation and Aftercare Service retains responsibility for the resettlement of offenders, operating a range of services including probation hostels that provide therapeutic services and vocational training (Obondi, 2010).

Rehabilitation

Offering a broader range of interventions, rehabilitation practice encompasses the objective of enabling former offenders to reestablish themselves with their families and communities, and to become productive contributors to society. Interventions under this heading may incorporate assistance in seeking training or employment opportunities, support to address problems such as substance misuse, counseling and family support, resolving problems linked to offending, and personal advice and support.

The origins of the rehabilitative ideal can also be located in nineteenth-century industrial societies, with the establishment, for example, of the police court missionary service in England and Wales in 1876. Rehabilitation was not seen simply as a matter of solving the practical problems faced by exoffenders, but of redemption; it was 'for the good of their souls, as well as to reduce the harm they would otherwise continue to do themselves and others, such as their families' (Raynor and Robinson, 2009: p. 5). Importantly, the rehabilitative perspective focuses on providing 'treatment' to address the underlying causes of crime, presumed to be located squarely with offenders themselves, whether these be associated with educational deficits, mental health problems, or possibly substance or alcohol misuse (Patterson, 2012: p. 11). The concept of treatment sat well with the emerging emphasis on psychotherapeutic interventions as social work developed and became increasingly professionalized during the early to mid-twentieth century. This strand of thought remains influential in shaping models of intervention directed at changing the lives, capabilities, and circumstances of those whose criminal behavior gives cause for concern.

The 'Good Lives' model of offender rehabilitation, for example, is organized around developing the strengths and abilities of those undergoing the program:

> Intervention should be viewed as an activity that should add to an individual's repertoire of personal functioning, rather than an activity that simply removes a problem, or is devoted to managing problems, as if a lifetime of restricting one's activity is the only way to avoid offending. (www.goodlivesmodel.com, accessed 18.06.13.)

Socialization

A strand of practice has emerged that takes a more behavioral approach to resolving the difficulties faced by offenders, and relies on the assumption that there is a direct connection between behavior change and improving well-being. Under

this heading, for example, interventions may include social or life skills training, anger management programs, offending behavior programs, and other forms of behavioral intervention designed to reduce or eradicate problem behaviors, using either positive or negative reinforcement (Madoc-Jones, 2008: p. 132). These interventions are geared not primarily toward promoting the individual's welfare, but to ensuring that they are reintegrated into society as 'good citizens.' The assumptions behind this kind of approach incorporate the notion that behavior can be learned and reinforced either positively or negatively, and that 'problem behavior' is simultaneously socially undesirable and contrary to the best interests of its perpetrator. As behavioral interventions themselves have become increasingly central to the social work repertoire, so they have equally come to be seen as particularly suited to the challenge of seeking to inhibit antisocial tendencies. As early as 1964, studies were being undertaken into the effectiveness of positive reinforcement, and reporting beneficial outcomes (Trotter, 2009: p. 143).

Increasingly, this form of intervention has come to be associated with the notion of 'prosocial modeling', based on the assumption that positive reinforcement is known to be more effective than behavioral programs based on negative sanctions. This term is

> interpreted… broadly to include a group of skills which include supervisors modelling pro-social values, reinforcing clients' pro-social expressions and actions and negatively reinforcing or confronting pro-criminal actions and expressions of those clients'. p. 142)

Restoration

Another relatively recent development has been the emergence of restorative justice, which arguably represents a contemporary attempt to integrate social work methods with the expectations of the justice system. Unlike other approaches, which are concerned with changing aspects of offenders' behavior or circumstances, the focus here is on the offense and the 'harms' arising from it. Interventions are geared toward problem solving, and enabling all those affected by the offense to come together to achieve a negotiated settlement. The offender has an opportunity to 'put right' the damage done, and also, in doing so, to be 'reintegrated' and effectively forgiven by the community. Restorative justice derives substantially from the experiences of societies seeking to achieve reconciliation following periods of conflict, and it is informed by a commitment to utilizing the justice process to rebuild and support healthy communities.

The modern widespread adoption of restorative justice practices is commonly attributed to the (re)discovery of a historic Maori tradition, grounded in principles of community justice, consultation, and settlement of any damage done: "consultation between the parties would take place as to a suitable way of dealing with the matter, so as to heal any hurts and restore things to 'normal' again" (Considine, 2003: p. 153). The 'healing' process offers a means to secure reconciliation and reintegration for the offender, at the same time as the offense victim's needs are directly addressed. The interests and voices of the offender and victim are brought together and considered in tandem, so that both sides are enabled to gain from the resolution process, and the well-being of the community in general is enhanced.

> Through restorative justice, the dignity of both the offender and victim are maintained through a process that is the opposite of customary criminal justice proceedings… The focus of restorative justice is on the offender's whole personality, not only on the acts that have caused the harm. Ideally, this informal but emotionally intense process will have a humanizing effect on all participants. (van Wormer, 2002)

Welfare + Rights

An alternative approach to social work in criminal justice, albeit relatively underdeveloped, is based on principles of 'welfare + rights,' underpinned by the recognition that many offenders are significantly disadvantaged, and that it is only through a process of empowerment and capacity building that they will be able to overcome the inequalities that are associated with their criminalization. In other words, social work practice with people in the justice system should not collude with the labels associated with their status, but should work with them to ensure that they are able to challenge the discriminatory processes they experience.

Scraton and Haydon (2002), for example, have argued for a 'positive rights-based welfare approach' to intervention with children in the criminal justice system; and the Howard League has developed a form of intervention with young people, which is a form of enhanced legal service, combining 'welfare + rights' (Smith and Fleming, 2011). While the principles of a rights-based approach are quite widely accepted, as in South Africa, for instance, implementation is much more tentative and precarious (Stout, 2008). Wales, too, is reported to have made progress toward a more inclusive and participatory approach to the delivery of youth justice (Nacro, 2009).

Social Work, Criminal Justice, and Antidiscriminatory Practice

As the 'welfare + rights' perspective recognizes, the argument for a social justice approach is further supported by the principles of antioppressive and nondiscriminatory practice, which are so central to social work (Dominelli, 1988). Not only is criminalization itself associated with inequality and discriminatory treatment, but the justice system, too, is characterized by practices that lead to additional harms.

Figures from the United Kingdom, for example, demonstrate that black young people are significantly overrepresented in the justice system (Ministry of Justice, 2010). This is also confirmed as a widespread problem internationally by the Global Commission on Drugs Policy (Stevenson, 2011). Discrimination is evident, too, in other respects, as the profile of those who make up the population of officially recorded offenders is shown to be very different in many respects from the population in general, for example, in respect of previous care histories, learning and communication difficulties, mental health status, income, and class background. Against this backdrop, it seems clear that social work with offenders must incorporate a commitment to advocacy and action on

behalf of those who experience the discriminatory effects of being criminalized, as well as the harms that are sometimes associated with the activities of the justice system itself (see Carlile, 2006, for example).

'What Works' in Social Work in Criminal Justice Settings?

There has been a considerable emphasis in recent years on the importance of providing evidence of 'what works' in criminal justice interventions, as in other areas of welfare service delivery. This is often narrowly defined in terms of reoffending rates, to the exclusion of those aspects of change in people's lives that might be thought of primary interest to social workers, such as improved quality of life, well-being, and social inclusion.

It is argued, for instance, that it may be unrealistic to expect probation supervision to make a substantial contribution to a reduction in reoffending, but it can help to build 'human capital' through provision of practical help, to increase employment prospects, or to improve family circumstances (Farrall, 2002). McNeill (2006) also argues that a narrow focus on correctional aims and methods is counterproductive, and unlikely to succeed even in its own terms. He argues instead that "some things 'work' with some people some of the time" (2006: p. 130), and this is perhaps unsurprising given the diversity of circumstances, characteristics, and needs represented by those who come into contact with the justice system. Instead,

> It is a recurring finding that no method of intervention is, in and of itself, any more 'effective' than any other; rather, there are common features of each intervention that are most likely to bring about positive change… These 'core conditions' of effectiveness include: empathy and genuineness; the establishment of a working alliance; and the adoption of person-centred, collaborative and 'client-driven' approaches. (McNeill, 2006: p. 131)

In other words, whether the objectives are to reform offenders, or to improve their lives and meet welfare needs, it is the application of core social work values and methods that will provide the basis for effective interventions. The precise nature of the intervention should be guided by the context and specific features of the offense in question, but the underlying principles and strategies should be derived from recognition of the need for inclusive practice based on a spirit of partnership and empowerment.

Social Work and Criminal Justice: Where Are We Now?

While there is some evidence from the typology and practices outlined above that social workers have taken a proactive and creative approach to negotiating a place for welfare practices in the criminal justice system, it also seems that this has been (and will be) a continuing struggle between those perspectives that locate 'the problem' with those identified as offenders, on the one hand, and on the other, those perspectives that recognize the role of social systems and structures in the process of 'constructing' criminals. The attempt to assert and establish the legitimacy of a distinctive language of welfare, need, and indeed, rights, against a system preoccupied with risk, responsibilization, punishment, and control will remain problematic. Where it has been possible to achieve an accommodation, it is usually on the grounds that a distinctive group (children, people with learning difficulties, or those with mental health issues, for example) are entitled to special treatment on the grounds of 'diminished responsibility'. For those who are held fully accountable for their actions, the case for welfare intervention is much harder to make and is reflected in practice by the continuing erosion of the social work element of probation service practice, internationally (Burke, 2011).

In accepting a place in the justice system on the basis of identifiable 'vulnerability' or 'special needs,' however, social work puts itself at risk of colluding with wider discriminatory processes and systemic disadvantage, and undermining its own core values. Whether or not some individuals and groups have particular needs, social work practice should not lose sight of the fact that the criminal justice system itself generates needs and creates problems for those who come into its ambit, and that therefore there is a legitimate place for welfare intervention and advocacy across the entirety of that system. When social workers identify aspects of the justice system as oppressive and in breach of human rights, then as a profession social work has a responsibility, in line with its core values, not to collude with, but to challenge unfair and discriminatory treatment of those classified as 'offenders.'

Abstract

The relevance of sociology to the study of criminal justice is assessed and analyzed. The Criminal Justice System (CJS) is conceptualized and linked to broader sociopolitical factors and influences. Components of the CJS are examined in light of sociological perspectives. Trends and directions of research, theory, and policy formation are explored.

In the last 40 years and especially since the turn of the twenty-first century, the study of criminal justice (CJ) has burgeoned with increasing numbers of programs at all academic levels devoted to this specialty. This trend has resulted in a progressive growth of CJ doctorates and concomitant reductions in the influence of other disciplinary professionals on the course and trajectory of theory, research, and policy formation in the field. While sociology departments have retained perhaps the most substantial outsider effect on CJ study of all disciplinary approaches, some scholars suggest that this is a time-limited effect that will diminish as CJ establishes its full autonomy (Wrede and Featherstone, 2012). Alongside the remarkable development of CJ programs, sociology departments have retained much of their criminology curricula, resulting in extensive duplication of content (Maddan and Hartley, 2011). Students and scholars with a greater policy orientation tend to gravitate to CJ specialization while sociological criminologists, especially those theoretically inclined, tend to study the contextual, ideological, and cultural dimensions of both crime and its study by CJ practitioners (Hauhart, 2012).

This article will utilize sociological perspectives to examine: (1) the roots of the idea of a criminal justice system (CJS); (2) the implications of this notion in practice; (3) its elements and functions; (4) its relation to the courts; (5) the distinction of crime and deviance; (6) implications for corrections; (7) the interplay of legal and medical models; (8) research priorities in the field; and (9) future directions in the CJS. The emphasis here will be on how a sociological approach affords certain analytical benefits not achievable from a purely criminal justice perspective. The intent here is to demonstrate the independent utility of a sociological study of criminal justice while not challenging the legitimacy of the concrete study of this area. A distinction should be drawn at the start between criminal justice as a study and the CJS. Criminal justice studies the CJS for the purpose of preparing and informing practitioners, enhancing the effectiveness of programmatic efforts to address the social problems of crime by providing data, explanation, prediction, and control. Its task is to support the criminal justice providing the broader and more fundamental surround within which criminal justice operates as both study and system. To posit that there is in fact a CJS is to construct it ontologically as an interconnected, interactive, functional feature of a broader social system. Whether criminal justice does indeed function systemically is itself a very general but still empirical question, which has yet to be fully or persuasively established by the field of criminal justice study. Indeed, the legitimacy of criminal justice study does not depend on the actuality of the CJS, but it does generate a paradigmatic approach that an emerging field of theory and research might use effectively to organize its agenda.

The Origins of the Concept

CJS is a fairly recent acquisition of the scientific and professional vocabulary. Since the publication of the United States, President's Commission on Law Enforcement and Administration of Justice report 'The Challenge of Crime in a Free Society' (1967) (https://www.ncjrs.gov/pdffiles1/nij/42.pdf), the term has been used with a somewhat precise meaning.

However, in the process, the Commission's investigation led to the claim that the goal of the 'war on crime' – the fight against insecurity and the foundation of public safety of the persons, goods, and moral integrity of the citizenry – necessitated a comprehensive concept inclusive of all the institutions concerned in this objective. The breadth and complexities of this conceptualization led to the identification of incongruities between some of its parts, allowing critics to call it a 'nonsystem,' referring to the apparent incoherences and contradictions in the functioning of the overall system.

It became evident for the Commission that there existed a real and a virtual interrelationship, reflecting an interdependency between legislations, institutions, organizations, and scattered offices throughout the machinery of criminal justice, whose goal is the maintenance of public order, the safeguard of liberty, physical integrity, and concern for the victims of the failings of the protective shield, extended by the law and protected by the Constitution. Recognizing these historically and nonlogically ordered institutions, laws, services, and so forth, the Commission wanted to give a degree of coherence to all of them in order to secure a better, more efficient coordination, built around a common goal: assuring, under the supremacy of the law and the Constitution, equal justice and protection to everybody. Despite the criticism, the concept of the CJS was born. Thanks to this organizational principle (a 'system' necessitates some logic), overlapping jurisdiction, duplication of services, and irrelevant goals or functions were identified. The Commission's logo – with its input and output/entrance and exit design – illustrated graphically how, from arrest to release, from sentence to punishment, the whole process of

criminal justice constituted an administrative and logical 'whole.' This holistic approach provided the reformer with a blueprint and a compelling agenda for reform.

However, these origins of the CJS should not hide the basic fact that the inspiring and commanding center of their systematizing approach can be understood as a development of the *code d'instruction criminelle of 1808*. This code was characterized by: (1) rigorous penal procedural rules; (2) the availability of material and technical conditions to implement those rules; (3) a reasonable degree of coherence among the constitutive elements of the system, principally the offices of the prosecutors, magistrates, and other officers of the judiciary. Similar transformations took place in other Western countries that incorporated a systematic approach. The principle of the separation of powers, the presumption of innocence, and the independence of the judiciary were nowhere threatened by the emergence of the CJS, with the notable exception of course in the totalitarian countries.

Practical Impact of the Concept of the CJS

A radical transformation in public administration began as early as the middle of the nineteenth century, accelerating after World War I and continuing beyond World War II. One result was the emergence of an activist and interventionist social policy. A similar transformation in criminal justice administration did not occur until later. In the process of its consolidation, it confronted the cultural revolutions of the 1960s and 1970s, and even some basic principles of the penal procedural law underwent some changes.

Among the consequences of the development of legal structures and philosophies were a loosening up of the system, allowing an increased role for a defense attorney (human rights legislation had a major impact on the proactive role of the defense councils), and resulting in an increase in the burden carried by law enforcement agencies to accommodate the increasing demands of defense attorneys as well as rules edited by commissions of human rights (the need for 'foolproof' proofs required by tribunal became more cumbersome and proceedings slowed down notably). The increase of the workload in the prosecutor's offices, as well as at the courts, was not in step with the necessary budgetary requirements allowing a decent discharge of the increased workload devoluted to the CJS in charge of the 'postarrest' phases. The well-known, yet little understood, consequences of overloaded courts; plea bargaining; vagaries of correctional strategies, inequalities, and extravagant; burdensome cost increments escalated from the 1980s onward.

Additionally, there was a growing incoherence between segments inside the diverse components of the CJS. Undue competition has arisen between services, which should have been submitted to rules prescribed by their common goals. Moreover, a growing politicization has taken place. The power of unions is increasing everywhere: the judges, the prosecutors, and the police are organized in their own unions, and correctional officer unions in some states, particularly in California, constitute major veto groups. Some unions of magistrates, particularly in France and Italy, are playing an active and sometimes radical role inside of the CJS. Thus the coherence of the CJS has suffered from the centrifugal forces in its own ranks. This worldwide phenomenon is affecting open societies, and while the European continental nations, in-line with their centralizing traditions, are seeking new measures in tune with their traditions, all of them are also facing similar problems. Problems of CJS incoherence have become exacerbated by severe budgetary constraints since 2008, particularly in the US with its comparatively complex legal/juridical system, diverse demographics, diverging yet stringent crime philosophies, and harsher sentencing practices.

Components and Goals of the CJS

The 1967 Presidential Commission, which is *de facto* the originator of modern research on crime, delinquency, victimology, and criminal justice agencies, introduced and somehow accredited a rather artificial distinction between research carried out on the CJS and criminology. This discipline was related, if not assimilated, to etiological research on crime causation. Its continental origins were stressed. Criminal justice research, born of the common law tradition, postulated the existence and interdependence of all components of the CJS, including law enforcement, criminology, criminal justice administration, prosecutor's office management, sentencing guidelines for judges, and so forth (See Section Criminal Justice Research).

Many of the major changes that the CJS underwent are related to the sudden surge of the world economy and commerce in the direction of globalization. Accordingly, the problems facing the CJS became global, embracing the whole world. One has to face the fact that crime and justice have to be addressed in an open world, at the level of the global economic and financial system working with the tools of the newest information and technology. The sociopolitical system and the political power structures are closely related to the new financial, commercial, and economic trends and powers. The magnitude of the challenge facing all the components of the CJS is tremendous. Consider, after 1980, that the volume of the sales of foreign stocks and bonds increased drastically on the market (Adler et al., 1994). Moreover, capital movements, legal and nonlegal labor migrations, corporate alliances and partnerships, proliferation of tax havens, money-laundering practices and controls, cyber attacks, hacking, pirating, and so forth, have rendered many crimes global in nature.

However, many countries are largely decentralized and have residues of common law traditions. There, the integration and internal coherence of the CJS is limited; rather the tendency is toward internal incoherence and diversity. Thus it is not surprising that these countries, illustrated by the USA, are much slower to ratify or contribute to international criminal and penal jurisdiction. An example is the US government's refusal to adhere to the Rome convention sponsored by the UN to create an International Criminal Court (ICC) although a working relationship of engagement has been established since 2010 (http://www.state.gov/j/gcj/us_releases/remarks/2010/143178.htm). In the second decade of the century, the US has extended greater efforts to collaborate with international bodies such as ICC but a delicate line has to be threaded

due to both the mode of operation of the utter complexity US crime control policy and political imperatives and ideologies.

CJS and the Courts

In this context of global integration, the thrust toward internationalization increasingly impacts local crime scenes (arms dealing, Internet crime, terrorism, migration, etc.) so that, directly or indirectly, they become integrated into international activities through the operation of offshore banking; industrial espionage; unofficially sponsored hacking into corporate, financial, and national security institutions among other devices; intermingling, sometimes, with secret service operations (e.g., 'evidence' of Saddam Hussein's WMDs) (Weiner, 2008); and with illegal merchandising or human trafficking, tax frauds, illegal financial contributions to political campaigns or parties, and so forth. Money laundering is the lifeline of all these criminal and illegal activities. Out of necessity, a new international CJS is emerging with the support of the UN and the European Union (EU) (http://www2.icc-cpi.int/Menus/ICC/About+the+Court/). Other tribunals in Africa and Asia are in process of being established. Especially in the face of international terrorism, support for such tribunals is growing in the US along with opposition to internationalization of the CJS (http://voices.yahoo.com/moving-towards-international-criminal-justice-system-649697.html).

One can see that open democratic societies are building new lines of defenses using legislations and sharpening legal tools available to the police and prosecuting attorneys. A new Europe-wide legal system is being created and is slowly and systematically building structures and defenses, which are both reactive and proactive. The building of such a coherent system was, in part, a response by the CJS to challenges initiated in continental countries under the auspices of the EU (http://www.haguejusticeportal.net/?id=2). Threats to the Euro currency by failures of and fraud by financial institutions, national banking crises, and fear of extreme exchange rate fluctuations also are precipitating higher levels of cross-national collaboration than in previous decades.

The Debate on the Definition of Deviance and Criminality

In the 1970s, sociology questioned what distinguishes a 'criminal' act from a 'deviant' one, thereby adding a substantial burden to the functioning of the CJS. Such questioning created difficult dilemmas for the CJS, whose task is to enforce the existing laws. Problems arose as to where to draw the limits of the interventions of the jurisdictions of the CJS agencies in controlling or repressing the 'criminal' and unlawful activities of large, and certainly vocal, minorities. The frontiers between crime and deviant behavior became blurred. The law enforcement agencies, occupying the first line of defense in securing public safety, became hesitant in the application of the law. This environment of questioning and doubt encouraged the increasing activism of human rights defense groups, critical of the law. And when the police tried to enforce questionable laws, they were frequently confronted by activist groups, sometimes with violence. Many court actions followed violent confrontations in the streets. Also, accusations against the police for being prejudicial created a major impediment to efficient policing.

Variations in local CJS and community relations, contrasting values between law enforcement personnel and civilians, and inconsistencies of enforcement, prosecutorial, and judicial and correctional policies have all contributed to confusions, conflicts, and unpredictability of the entire range of crime response approaches. External review boards, internal examiners, accountability requirements, unending assessments, and so forth all encumber the task of securing public safety within a civil rights framework.

The manifold increase in the charges burdening the prosecutor's offices, mainly in major cities, reflected itself in the overflow of cases brought in front of the judges. Plea bargaining before the trial (essentially a kind of out of court settlement between the prosecutor and the defense council) became an accepted way of proceeding. For several decades it has been the only expedient to avoid the complete paralysis of the whole judicial process. These plea bargains have resulted in some gross miscarriages of justice that have become broadly recognized (Bibas, 2004).

Morally as well as legally, and sometimes clearly illegal, plea bargaining is still currently and fairly widely practiced in the US courts system. One notes that sociologists frequently criticize this practice, while many CJ professionals accept the expedient as at least a necessary one. Certainly in the US there is more support for plea bargaining than elsewhere (http://www.debate.org/opinions/does-plea-bargaining-undermine-the-criminal-justice-system). In contrast to the US, these practices are strongly rejected by the European continental legal system, but the future of its integrity remains an open question. The caseload of the courts is increasing constantly and political power negatively confronts the judiciary in several important Western European countries. The main issues are political corruption, bribery, financial deception, and abuse of power. We have yet to see the outcome of this type of conflict inside of the continental system where political power negatively confronts the CJS.

Changes in the Philosophy of Punishment

Imprisonment was a notable advance over the all-too-common previous method of punishment: the death penalty. Virtually from its beginnings imprisonment developed in response to religious concerns (largely from nonconformist denominations – Methodist, Congregationalist, Presbyterians, Quakers, Baptists, etc.), and was informed by ideas of the continental Enlightenment, as well as English social contract and utilitarian theories, and the views of Scottish moral philosophers.

In the north-east sector of the US these religious and intellectual forces combined to encourage a massive social experiment in punishment, which was grounded in the emerging belief that humans are social beings possessing 'natural' or inalienable rights, capable of reason, and inherently good or virtuous: the infant cannot be evil. From this perspective, the logic of imprisonment would not only punish the wrongdoer,

but seek also to rehabilitate that wrongdoer, as well as to deter others. Elmira, Auburn, and Cherry Hill were famous attempts to express this evolving penal philosophy, and de Tocqueville's tour of these institutions was an example of European continental interest.

This complex and integrated humanistic view, issuing from the Enlightenment, was challenged by developments in sciences such as medicine and psychiatry. These disciplines understood criminal acts to arise from personality disorders rooted essentially in social, biological, or psychological conditions. In a sense, the 'medical model' retained but transformed elements of the 'humanistic model.' The goal of rehabilitation was retained, but its justification was to be found and legitimized in scientific methodology. One consequence of this scientific approach, as it gained influence, was to impact the CJS through legislative reforms and judicial practices, for example, the rapid spread of indeterminate sentences, and the transferal of the principle of rehabilitation from being a concern of the larger society (religious activists, legislators, educators, etc.) to become the concern of scientific practitioners encompassing all sorts of therapies, treatments, and rehabilitative initiatives.

Emergence and Hegemony of the Medical Model: Conflicts of Goals with the Legal Tradition

The nature of the scientific method is the permanent questioning of existing proofs and practices. For example, in medicine, it results in a continuing revision of therapeutic practices and rehabilitative techniques. Naturally, a continuing tension and conflict develops between the ever-changing medical therapeutic approach and the desire of the CJS to retain humanistic principles of equity, rights, and equal treatment before the law. This situation threatens its coherence and creates an increasing vulnerability for the CJS, especially to its claims of legitimacy.

The challenge to legitimacy was not limited to the confines of the CJS, but permeated the entire open, pluralistic, humanistic society. Everywhere, a profound crisis of values occurred: in the family, and in institutions of authority, including the medical and academic communities. The identification of who or what was responsible for this turmoil emerged from a variety of diverse sources, making it impossible for a generally agreed upon understanding to be reached, and so disarray prevailed.

The impact on the CJS, which became closely associated with the medical model, was disastrous in that it allowed for both an immunization of the 'underclass' against claims of criminal behavior, and the emergence of new prophets with new social and cultural constructs. An attempt to correct this situation, and to devise a means of bridging the chasm separating the reality of crime and the CJS, was Von Hirsch's (1976) doctrine of 'just deserts.' This doctrine compromised law and order while accommodating the new forms of behavior. The end result was a temporary compromise in which the CJS maintained and protected the core values concerning material and personal security, while adapting itself to the demands of the 'post-Woodstock' society.

Reactions counter to the delegitimation process rose in the 1990s and dominated thinking for about 20 years. This reaction emphasized a return to a simpler certainty about the proper response to crime with determinate sentencing, reduction of funding for rehabilitative and educative focus, de-emphasis on alternative correctional approaches, treating juvenile offenders as adults, etc. More recently, efforts have been directed toward addressing deep and long-term concerns regarding overcrowding, high rates of recidivism after long sentences, juvenile transitioning to adult crime, funding reductions for corrections, gun violence, victim support, and punitive approaches to drug-related offenses (http://www.thecrimereport.org/news/inside-criminal-justice/2012-04-crime-and-justice-in-america-1975-2025).

Criminal Justice Research

While criminological research of a sociological stripe has focused on etiological areas, CJS research has been primarily institutional. As in all such distinctions, the differences in fact are less determinative than in definition. 'Corrections,' a new designation for penology, was a major aspect of research on the CJS. These distinctions also reflect a growing attention to the evolution of ideologies, to new tendencies of penal philosophies, justifying research on alternatives to the actual CJS, which answers to the needs of victims and new sentencing philosophies. The analysis of the performance of the CJS, evaluation of alternatives for this system, and all kinds of innovations, were also an integral part of research on the CJS. Also, the treatment of offenders, their resocialization, programs of crime prevention, and experiences with 'restorative justice' became the spearheads of research in criminal justice.

Some Future Perspectives

The real and symbolic ruins that were the reality of the CJS under the conditions of this temporary compromise were, fortunately, addressed by H.L. Packer (1968). Packer identifies two models. The first is the 'due process model,' characterized by the jurisprudence of the Warren Court, in which most of the odds were placed against the defender of public safety and order. This model amplified the 'rights' of the individual, and encouraged a critical, reactive attitude on the part of the judiciary. This model has a rule-oriented rather than a substantive-oriented approach.

The second is the 'crime control model,' which emphasizes the existence and exercise of official power. Its validating authority is ultimately legislative (although approximately administrative). It can be viewed as consistent with, and a continuation of, humanistic-Enlightenment principles. In light of the lessons of the eighteenth century, and because Packer's theories are deeply rooted in humanistic-Enlightenment principles and now associated with conservative political orientations, his crime control model prevailed in the recent past but has come up against popular sentiment that counters mass incarceration, particularly for nonviolent offenders. A synthesis of models seems to be taking shape as crime control remains a significant concern, especially in relation to transnational crime, while alternative means of criminal justice are coming to the fore, including drug courts, restorative justice, community-based corrections, electronic supervision, community and military service, etc.

Conclusion

In conclusion, the contributions of the social sciences to the CJS are varied. In continental Europe, the social sciences, as an academic discipline, had limited influence, notwithstanding contributions of outstanding scholars. In North America the social sciences have established a strong academic position and exercised a direct influence on the CJS. This influence also included a contribution to the intellectual and moral crises, which characterized the 1960s and 1970s. This was largely due to an epistemological crisis, which shook the very foundations of social and behavioral sciences. Whether or not they will recover their empirical scientific tradition is still an open question.

That crisis has largely been resolved in the intervening decades as varieties of criminological and criminal justice studies have applied postmodern, poststructural, cultural, peacemaking, radical perspectives, etc., as well as conventional crime control approaches in numerous and proliferating theoretically informed empirical studies. As the study of the CJS has grown and absorbed diverse tools, sociological influences have both expanded and occupied a distinctive, even privileged location in this emergent, no longer nascent field (Eagle and Barnes, 2008). Alongside other disciplines including psychology, anthropology, biology, sociology have contributed substantially to the advancement of criminal justice study and to the CJS itself, and will continue to do so deeper into the twenty-first century.

Criminal Liability and Criminal Defenses

Abstract

All countries have criminal laws. Those laws define certain behavior that is forbidden – not just any behavior, but behavior that violates a country's core values and interests. Criminal laws also set out the punishments for those who violate the criminal laws without lawful authority, justification, or excuse. This article examines the principles that govern criminal liability and the defenses that allow a person to avoid conviction and punishment. A fundamental principle of criminal liability is that no person shall be convicted of a crime unless that person has the ability to reason right from wrong and the freedom to choose whether to do right or wrong. Many specific defenses find their rationale in these dual abilities. Put another way, there must be both unlawful conduct and an unlawful state of mind when engaging in that conduct. With that in mind, this article will look at defenses of automatism, sleepwalking, and other forms of involuntary conduct, mistakes as to an essential element of an offense, intoxication, insanity, provocation, duress, and justifications such as use of lawful force, self-defense, and necessity.

Criminal liability requires proof of three interrelated components: (1) commission of the prohibited conduct specified in the offense (also called *actus reus*), (2) committed with a particular mental state (also called *mens rea*), (3) without a recognized legal defense. Broadly conceived, criminal defenses include all legally recognized factors or rules that prevent a person from being convicted of an offense. Defenses may negate the elements of *actus reus* or *mens rea*, or may operate notwithstanding the fact that a person has committed both the *actus reus* and the *mens rea* of an offense. This article begins with the observation that while there are a number of different legal systems in the world that differ very significantly in many respects, when it comes to basic principles of criminal liability and defenses, they are surprisingly more similar than different. After providing a few other preliminary comments on criminal liability, this article then provides an overview of defenses in general, including a bit more detailed analysis of a few defenses such as provocation, self-defense, and insanity, which have been particularly controversial in many countries around the world.

Preliminary Comments

Major Legal Systems and Criminal Responsibility

Today there are four major legal systems operating in different parts of the world, not counting Hindu law in parts of India's legal system and customary law operating in whole or in part in various parts of the world (Menski, 2006; Kritzer, 2002). Those four systems are common law, civil law, Islamic law, and socialist law systems.

With extensive colonization in the eighteenth and nineteenth centuries of North, South, and Central America, Africa, South Pacific, and Asia by England and other European countries, especially France, Spain, and Holland, the common law and civil law systems, and in particular their criminal laws, were adopted or imposed in most countries throughout these regions (Ferguson, 1998; Petchsiri, 1987). In many instances, these laws and legal systems remained in place after the colonizers left and the countries had declared independence. The legal systems noted above are different from one another in a multitude of ways, including substantively, procedurally, and institutionally. While each legal system has criminal (penal) laws, the procedures for investigating, prosecuting, trying, and punishing crimes are significantly different in many respects in each system. What is similar is that each country creates criminal laws that are designed to protect fundamental values in that country by forbidding certain behavior that threatens or violates those values. In this regard there is a lot of commonality between these legal systems as to basic crimes against persons and property (murder, rape, robbery, arson, fraud, etc.). On the other hand, there are significant differences in crimes against public morality, state order, and state security when one compares socialist, Islamic, and civil law/common law criminal laws (Butler, 2003; Zhu and Han, 2013; Lindsey, 2008).

In regard to the subject of basic principles of criminal responsibility, there is more similarity than difference between nations. All systems recognize the same three components for criminal liability: prohibited conduct (acts or omissions of legal duties), blameworthy mind, and absence of any legal justification or excuse (LaFave, 2003, vol. 1; Ashworth, 2009; Bohlander, 2009; Butler, 2003, Chapter 17; Badar and Marchuk, 2013). In short, each system operates on the principle that a person deserves to be convicted and punished when he/she knowingly and willingly violates criminal prohibitions without any lawful excuse or justification. Badar and Marchuk (2013) make this same point in their comparison of principles of criminal responsibility in common law, civil law, Islamic law, and socialist legal systems such as Russia and China.

Questionable Assumptions about Autonomy and Criminal Liability

The criminal justice systems around the world continue to base decisions on criminal liability and punishment on rather simplistic views of humans as rational and autonomous persons. For Kant and many other moral and religious

philosophers, the belief that humans generally have the capacity to reason right from wrong and the capacity to choose right or wrong justifies imposing criminal responsibility and punishment on persons who chose to do wrong.

Sadly, the law's current approach to autonomy or capacity to choose has remained largely unchanged for the past two or three centuries. In this regard, the law acts as if the past 150 years of social science inquiry and knowledge about human conduct had never occurred. The alternative notion that human behavior could be more a function of biology and environmental forces than free choice is a direct threat to a society's deep-seated need to blame someone other than themselves for criminal harms that occur (Bargh, 2008; Montague, 2008; Jones, 2003; Friedland, 1998; Johnson, 1998; Grant, 2006; Morse, 2004).

That is a form and degree of blame which most societies do not seem ready to accept. It is easier and simpler for a society and its law to assume that people who can reason – i.e., know what they are doing – can also choose to do or not to do the criminal act in question. In that sense, the individual who is found criminally liable is a convenient scapegoat for societal inaction or neglect. As Herbert Packer (1968: 74–75) famously said, "The law treats man's conduct as autonomous and willed, not because it is, but because it is desirable to proceed as if it were."

While the law may not provide a substantive defense – i.e., a full or partial acquittal – to a person whose criminal conduct is largely influenced by biological or environmental factors, our sentencing laws are somewhat more forgiving. A sentence is, among other matters, the law's denunciatory and punitive response to a person who has been found guilty of a crime and therefore deserving of blame for causing that criminal harm. External factors are often viewed as mitigating circumstances when a judge engages in the difficult task of determining a fit and proportionate sentence. Notions of individual blameworthiness allow for the consideration of at least a crude account of other influencing factors in determining 'how much' the offender is to blame and therefore 'how much' punishment he/she deserves (von Hirsch and Ashworth, 2005).

Criminal Liability and Defenses

Defenses negate criminal liability, either fully or, in some cases, partially. Thus defenses are central to a determination of criminal liability. There are a number of different ways to distinguish and classify defenses. The first way is to organize defenses with regard to how they operate on the three elements of criminal liability: they can negate the existence of the prohibited conduct, they can negate the existence of the requisite blameworthy mind, or alternatively they can apply notwithstanding the existence of the prohibited conduct and the required state of mind. Since the presumption of innocence normally requires the state to prove both the prohibited conduct and the blameworthy mind before imposing a finding of guilt, defenses that negate the prohibited conduct or blameworthy mind are also referred to as 'failure of proof' defenses in some jurisdictions (Robinson, 1984).

Secondly, defenses can also be classified as exculpatory and nonexculpatory. In other words, some defenses exist to reflect society's view that the actor does not deserve to be found criminally liable for his/her conduct because the actor's conduct or state of mind was exculpatory, i.e., not blameworthy in the circumstances in which the conduct occurred. For example, applying force to another person in lawful self-defense or while insane renders the actor's conduct exculpatory or nonculpable, i.e., not deserving of criminal liability and blame, albeit for very different reasons. On the other hand, some defenses exist notwithstanding the actor's blameworthiness. These defenses are justified on the basis of other policy objectives. For example, diplomatic immunity and statutory time limitations on prosecuting crime are two examples of nonexculpatory defenses. Those defenses exist to pursue policy objectives that are deemed to be of greater general importance than convicting an otherwise blameworthy actor. These defenses will not be further discussed in this article due to space limitations.

Thirdly, exculpatory defenses are sometimes further classified as either justifications or excuses. Justifications render *conduct* lawful and therefore not a crime; excuses render the *actor*'s otherwise unlawful conduct not deserving of punishment. Justifications focus on the *legality of the act*; excuses focus on *the blameworthiness of the actor* (Fletcher, 1978; Bohlander, 2009). The above three classification schemes for defenses can be a useful way to compare and contrast different defenses. However, these categories should not be seen as airtight compartments, and some jurisdictions, like Russia (Butler, 2003), do not subdivide their exculpatory defenses into justifications and excuses. In addition, the same defense may be classified into one category or another in different countries because the requirements for that defense can vary from one country to another (Robinson, 1984, vol. 1).

Overview of Defenses

The following overview of defenses is based primarily on the first distinction, namely the manner in which defenses operate in negating *actus reus* or *mens rea*, or operate notwithstanding the existence of *actus reus* and *mens rea*.

Defenses Negating *Actus Reus*

The *actus reus* or prohibited conduct of each offense is described in the statute creating the crime. Most jurisdictions have abolished unwritten common law crimes, though England is an example of a country that still has a number of them (Ormerod, 2011; Baker and Williams, 2012). Violation of prohibited conduct in a penal statute or code will constitute a crime unless there is a structural defect in the offense itself. Thus before being convicted of a crime in a code or statute, the offense in question must be lawfully enacted and proclaimed in force, not be applied retroactively, nor be unduly vague or a violation of constitutional rights such as free speech, privacy, and security of the person. If the offense in question passes those structural defenses, then the analysis of criminal liability will shift to the existence of the *actus reus*. The *actus reus*, depending on the crime in question, can be broken into the following elements:

1. an act and/or an omission of a legal duty to act,
2. which is voluntarily committed,

3. which occurs in the prohibited circumstances described in the offense, and
4. causes or results in any harm described in the offense.

In all legal systems, the prosecutor is normally required to prove each of these *actus reus* elements although there may be limited exceptions to that rule for one or more *actus reus* elements for some offenses. Thus a*ctus reus* defenses negate an essential element of the prohibited conduct and harm and they include the following:

1. *Not me*. The person charged does not deny that an offense occurred, but claims instead "it was not me who committed it." The accused may present evidence of an *alibi* (it could not be me, because I was in a different place at the time of the offense), or may argue that the eyewitnesses are mistaken, or that other witnesses are lying or that the forensic evidence obtained from the crime scene or from the accused is not conclusive in proving he was the person who committed the offense.
2. *No legal duty to act*. In general, criminal liability arises out of acts, not omissions, and this is particularly the case in common law countries. But all countries impose liability for some omissions. The question then is: in what circumstances does the law impose a duty on a person to act? For example, it is common in all countries to impose a duty on parents to provide care and protection to their children, or for a jailor, nurse, or guardian to provide care and protection to those in their charge. Failure to fulfill these legal duties will result in criminal liability if that omission facilitates or results in criminal harm. Common law countries (and some socialist system countries (Butler, 2003)) do not usually impose duties of care on persons who are not in a special relationship with one another. Civilian continental jurisdictions such as Germany (Bohlander, 2009) and France (Cairns and McKeon, 1995) do have broader legal duties to take action to save a stranger from serious harm or death if that action can be safely undertaken with little or no cost or inconvenience. But notwithstanding the differences in the nature and extent of legal duties in different countries, it is always a defense in every country if the prosecutor fails to prove that the accused omitted a legal duty imposed on him or her.
3. *The prescribed harm or circumstance has not occurred*. The definition of each offense sets out the harm or circumstances that must exist for that offense to occur. For example, the accused may have possessed sexually explicit material but that does not constitute the offense of possession of obscene material unless the sexually explicit material also meets the legal definition for obscenity in that particular country. Likewise, the offense of assault causing serious bodily harm is not proven if the complainant only suffered minor harm as a result of the accused's assault on him. Thus denial of the prescribed harm or circumstances is a very offense-specific defense.
4. *My act or omission did not cause the prescribed harm*. Some offenses only exist in circumstances whether the accused's act or omission has caused the prescribed harm. For example, the various forms of unlawful homicide – whether murder, manslaughter, or death by criminal negligence – all require the accused to commit an act, or omit a legal duty, that causes the death of another person. Thus if a wife secretly administers a deadly poison to her husband with the intention of collecting money from his life insurance policy, but the husband dies from an unrelated heart attack before the poison takes effect, then the wife's act of poisoning did not cause or contribute to the husband's death. Much more difficult causal cases arise in law when the accused's conduct has played some role, but not the primary role, in causing the prescribed harm. Different countries have different standards for 'how much causal connection to the prescribed harm' is required in order to hold a person criminally liable for that harm. Clearly the accused's act does not have to be the only cause, or the main cause. In many countries it is sufficient if it is a substantial and operating cause, or a significant contributing cause, or a real cause, or a proximate cause, or a cause that is more than trivial. If the accused's conduct does not meet a country's requisite causal standard, the accused is not guilty of that particular offense.
5. *My act or omission was not voluntary*. It is a widely accepted fundamental principle that acts or omissions are not criminal unless they are voluntary. But the word voluntary has a narrow legal meaning in this context. It refers to physical voluntariness in which the accused's conduct is a willed, physical act or omission in the sense that the person has consciously chosen to act or omit to act. By that definition, the accused's conduct is not voluntary if it is performed while the accused is unconscious or sleepwalking. Involuntary unconscious conduct is also referred to as automatism. Conduct can also be involuntary in some cases even though the accused is conscious, such as where the action is caused by a force beyond the actor's control.

Defenses Negating *Mens Rea*

For several centuries a Latin maxim has been used in many legal systems to capture two of the essential requirements for criminal liability – *actus non facit reum nisi mens sit rea*. Literally translated, this means "the act does not make it a crime unless the mind is also criminal." This maxim encapsulates the fundamental principle of fault – acts or omissions that cause harm are not subject to criminal liability unless they are done with a guilty mind. While the precise meaning of a guilty mind has changed over the centuries, there are nonetheless two broad categories of mental fault: (1) subjective and (2) objective. Subjective fault normally includes intention and recklessness. In cases of intent, the accused knows what he/she is doing and knows that it may cause or bring about the prohibited consequences or circumstances. In doing the act, the accused means to or intends to cause the prohibited harm. In cases of recklessness, the accused foresees the harm as a possible consequence of his conduct but does not necessarily want the harm to occur. Nonetheless the accused does the act for another purpose, recognizing that it is either possible or probable that the prohibited harm will also occur as a result of his actions. If the harm does occur, the accused has recklessly caused it.

On the other hand, objective fault does not focus on the accused's knowledge or state of mind, but rather the state of mind that a reasonable person would likely have if he/she

engaged in similar conduct in similar circumstance as the accused did. Objective fault is most frequently referred to as negligence. Serious crimes (or felonies) generally require subjective fault. If a legislature creates a serious crime punishable by objective fault, it is normally assumed that the requisite degree of negligence must be quite high – i.e., gross negligence or criminal negligence. Less serious crimes may require either subjective or objective fault depending on the nature of the offense and the words in the statute, creating the offense. In addition, where less serious offenses require objective fault, that objective fault may be of a lower level than criminal negligence. Ordinary negligence – i.e., lack of reasonable care or due diligence – may suffice. Thus in looking at defenses that negate *mens rea*, it is essential to determine whether the offense in question requires subjective or objective mental fault, and then to determine the exact form and nature of the requisite subjective or objective state of mind. The following defenses negate *mens rea*.

Mistake of Fact as a Defense

For subjective *mens rea* offenses, if an accused has made an honest mistake of fact in respect to one of the essential elements of the offense, the accused does not have the required *mens rea* and therefore he is not guilty of that offense. For example, the essential elements of theft are (1) taking (2) property (3) that belongs to someone else (4) without that person's consent. If an accused takes an umbrella from an umbrella rack at work thinking it is his umbrella, he *intends* to take the umbrella, but he does not *intend* to steal it. His mistake of fact in respect to element (3) of the offense (he thinks the umbrella is his) negates the intent to steal. But not all mistakes of fact provide a defense. Suppose an accused has always wanted a black umbrella. When an opportunity arises, he takes an umbrella thinking it is black and knowing it is not his and that he does not have the owner's consent. Suppose he is color blind and by mistake takes a blue umbrella thinking it is black. The accused's mistake of fact as to the color of the umbrella is no defense. It is true that he did not subjectively intend to steal a blue umbrella. However, proof of the color of the stolen property is not an essential element of the offense of theft; therefore a mistake as to its color does not negate the *mens rea* for theft.

While a mistake of fact as to an essential element of an offense is a defense, it can sometimes create a *mens rea* dilemma. Suppose the accused took the umbrella honestly thinking it was his, but his mistake was very unreasonable (i.e., a reasonable person in his position would have immediately recognized it was not his umbrella). Theft requires subjective *mens rea* – the accused must know (or suspect) that it is not his umbrella. In this example, he did not know it was someone else's umbrella, even though his mistake was negligent (highly unreasonable by an objective reasonable person standard). The dilemma then is whether the objective fault level of negligence can be used to satisfy the subjective *mens rea* required for the theft. Generally courts have said no and acquitted the accused of theft in those circumstances, but there have been odd and unprincipled exceptions to that rule. Once again, the better solution is to acquit the accused of the subjective offense of theft and allow the legislature to create a new offense of negligent taking of property if they want to criminalize such behavior. This type of *mens rea* dilemma does not arise in the case of objective fault crimes since a mistake of fact as to an essential element of the offense must be both honest and reasonable before it can negate the objective fault for the offense in question.

Mistake of Law and Color of Right

Since at least Roman times, it has been declared in most legal systems that mistake or ignorance of the law is no defense to committing a crime. This rule made some sense when it was only applied to serious and well-known crimes (as was the case in Roman law). But the rule can be harsh and unjust when applied to thousands and thousands of regulatory or quasi-criminal offenses, which are now part of the modern industrial state and are not generally well-known, nor easy to find. The harshness of the rule that ignorance of the law does not excuse has been avoided in some instances by creating an exception to that rule. For example, the definitions of some property offenses have a defense of mistake of law built into them. The law of theft in many jurisdictions is defined as intentionally taking another's property without consent and 'without color of right.' Color of right is an honest but mistaken belief on the part of the accused that he/she has a legal right to take or possess the property. In effect, the common law has recognized that property rights are complex and that ordinary citizens might understandably be mistaken about them. So an honest mistake of law about property rights is a defense.

Intoxication

Much like insanity, intoxication as a defense has been the subject of intense analysis and debate over the past 200 years. Prior to that time, intoxication was not recognized as a defense and in some instances was seen as an aggravating factor. However as the importance of the mental element in criminal liability increased, so also did the analysis of what should be done if the accused lacks the mental element for that crime due to intoxication.

Intoxication can be involuntary (for example, when someone surreptitiously puts a drug in another's food or drink). But there are very few instances of an involuntarily intoxicated person committing a crime. If that does occur and the drug puts the accused in a state of automatism or unconsciousness, then the accused is not criminally liable because the accused's conduct in committing the *actus reus* of the crime was not voluntary. Alternatively, if the drug does not render the accused unconscious, but it results in the accused not having the *mens rea* for the offense committed, then the accused is entitled to an acquittal. The only difficult scenario is if the involuntary intoxication does not negate voluntariness or the requisite intent, but only loosens the accused's inhibitions so that he/she commits the offense in circumstances where he/she would not have committed it if he/she had not been drugged. Most legal systems provide no defense in that scenario. However, since the accused's ability to control his/her behavior was reduced through no fault of his/her own, justice may suggest that a partial defense, or at least a lower sentence, is warranted (Ferguson, 2012).

While involuntary intoxication is rare, voluntary intoxication is a very frequent condition in the commission of offenses. It does not usually reach the very high level of intoxication that

is necessary to negate voluntary conduct or the requisite mental element. Lesser intoxication is not a defense. However, in the relatively small number of cases when the level of intoxication is sufficiently extreme to render the accused's criminal conduct involuntary or unintentional, different jurisdictions take significantly different approaches to those circumstances.

Exculpatory Defenses That Do Not Negate *Actus Reus* or *Mens Rea*

There are a range of other exculpatory defenses that operate notwithstanding the fact that the *actus reus* and *mens rea*, for a specific offense, have been committed. Some of these defenses are justifications; others are excuses.

Justifications

Lawful Use of Force

There are many occasions where the law authorizes the person to use force where necessary to achieve a socially legitimate purpose. For example, a person is entitled to use force to defend himself or herself or others, or to protect their property from unlawful interference from others, or to enforce the law, such as making an arrest, or in limited circumstances to control or discipline children under one's care. The lawful force must be necessary and reasonable in the circumstances. In addition, reasonableness implies some degree of proportionality.

In the above instances, the intentional use of force meets the *actus reus* and *mens rea* requirements for assault, but if the force is lawfully employed for one of the listed purposes, that use of force is neither wrong nor unlawful in the eyes of the law; indeed it is seen as lawful and proper – justified – conduct.

What is considered reasonable and therefore justified varies from time to time and country to country. If a person uses more force than necessary in any of these justified circumstances, that excessive force is not justified and the person may be found criminally liable for its use. In some countries, excessive force in these circumstances is recognized as a partial defense; in other countries it is not. In countries where excessive force in justified circumstances is a partial defense, should that form of self-defense be classified as an excuse, rather than a justification?

Self-Defense

Self-defense is a common example of the general defense of lawful use of force. Its legitimacy as a defense comes with its own set of challenges and controversies. In particular, is a person who honestly but mistakenly believes he is about to be assaulted entitled to rely upon self-defense (Conde, 2008)? To what extent do notions of imminence of the unlawful assault allow or prevent preemptive use of force in self-defense? To what extent should self-defense be justified if it is not necessary in the sense that the person could safely retreat and thereby avoid using force against the potential assaulter? And finally to what extent should the force being used in self-defense be proportionate to the unlawful force that is threatened or being used? In other words, would a person in a wheelchair, or a weak and feeble person, be justified in shooting another person who was about to unlawfully slap the feeble person in the face in circumstances where the feeble person had no other means to prevent the unlawful slap? The law's response to questions of this sort reveals a fair bit about a country's cultural beliefs on community peace and protection of life (including the life of the unlawful attacker), as opposed to cultural beliefs that citizens have the right to stand their ground at any cost against unlawful aggression.

1. The issue of retreat vs 'stand your ground' has become a key issue in regard to self-defense laws in the United States in recent years. For many years, and in many countries, the law of self-defense did not authorize a person to defend himself by use of deadly force unless he reasonably believed that his life was at risk and that there was no other reasonable and safe option other than the use of deadly force. Thus, if retreat was a viable and safe option, a citizen was expected to retreat. The only exception was that a citizen did not have to retreat from her home, or in the language of the common law, her castle. These self-defense principles are incorporated in the U.S. *Model Penal Code*. But only a minority of states still adhere to those principles (LaFave, 2003). Led by Florida in 2005, and fueled by support from the National Rifle Association, the majority of states have adopted 'stand your ground' self-defense laws. Invoking the right to defend oneself and others, and the right to bear arms to do so, states have abolished the requirement to retreat if possible before resorting to the use of deadly force in self-defense. Critics of these new laws claim that they result in a net decrease in public safety, that they encourage aggressive violence under the guise of self-defense and that such laws are unnecessary in the sense that there is no data indicating that persons were being prosecuted unjustly for defending themselves.

Necessity

The defense of necessity contemplates that in particular circumstances criminal conduct may be necessary to avoid the occurrence of a greater imminent harm, if there is no other reasonable and safe way to avoid this greater harm. The accused is between a rock and a hard place and the law should expect him/her to choose the lesser of the two harms in working his/her way out of that situation. In many countries, necessity has been successfully used as a defense to breaking traffic laws (e.g., speeding) to escape from a murderous attacker or to rush a sick child to the hospital where there are no other reasonable options (e.g., no phone to call emergency services or no emergency services readily available). Likewise, most people would argue that a hopelessly lost hiker, who is weak, cold, and starving to death, should be entitled, if he stumbles upon a cabin, to break into it to obtain food and shelter. While the defense of necessity is considered an excuse in some jurisdictions such as Canada and England, it seems more appropriate to treat it as a justification when the person has no alternative but to choose between the occurrence of two harms and in that situation chooses the lesser harm. If the accused chooses the lesser harm, it seems to be the right thing to do and in that sense his choice of conduct should be seen as justified, as it is in the majority of countries (LaFave, 2003, vol. 2; Ghanayim, 2007).

2. Whether necessity should be an available defense when the harm caused by breaking the law is roughly equivalent to the harm avoided is a much more controversial issue. When the two harms at stake involve human life, great moral debates are unavoidable. For example, is a doctor justified

or excused if he/she separates conjoined twins when one twin will surely die, but without the separation both twins will die within a relatively short time because the other twin's heart is not strong enough to support both of them? Is a firefighter who is trying to put out a fire in a nursing home justified in closing a fire door between two sections of the building, if the fire door is the only escape route for a patient who is still in that section of the building and will be unable to open the door on his/her own? There is no limit to the number of compelling examples one can imagine of situations where a choice may have to be made between the death of one person in order to save one or more other persons. Thankfully these examples rarely arise in actual practice.

Excuses

Apart from justifications, there are other exculpatory defenses that do not make the accused's acts right or lawful, but do nonetheless provide a socially acceptable reason to excuse the actor from conviction and punishment for his/her otherwise criminal conduct. These excuses include (1) criminal exemptions for the insane and children under a specified age, (2) provocation (and in some jurisdictions a broader defense of extreme emotional disturbance), (3) duress, and (4) mistakes of law based on officially induced error.

Insanity

The insanity (or mental disorder) defense has been the subject of voluminous discussion and concern for the past 200 years. In some legal systems, insanity is treated as a negation of the requisite *mens rea*. The accused's intent to kill a person whom he falsely believes is a devil or an assassin is not treated in law as a sufficient *mens rea* because it is not formulated in a rational, reality-based mind. On the other hand, many legal systems treat insanity as an excuse, separate and apart from whether the insane accused had *mens rea*. In these countries, the accused's insanely formulated intent is treated as a legally adequate *mens rea* but the accused is nonetheless excused from criminal liability. That excuse is based on the finding that due to insanity he/she was unable to understand the nature of his/her conduct, or that it was wrong, or in some jurisdictions, that he/she was unable to control his/her conduct. (Whether insanity is treated as a negation of *mens rea* or as an excuse, that fact does not significantly alter its elements.)

The various standards used in different countries from time to time for meeting the insanity test have always been quite high. This means that the insanity defense seldom succeeds. Many accused who are mentally ill are convicted and sentenced to imprisonment because their significant mental impairment has not risen to the required heights to satisfy the insanity defense.

If insanity is proven (and many legal systems require the accused to prove insanity on a balance of probabilities), the judge or jury must return a verdict of 'not guilty due to insanity' or 'not criminally responsible due to mental disorder' or some similarly worded verdict. But the verdict of insanity is not an outright acquittal as other verdicts are. The insanity acquittee is often subject to further state scrutiny, usually by way of a subsequent judicial hearing to determine whether the person is a continuing danger and therefore needs to be committed to a psychiatric institution or needs to be subject to other forms of control in the community.

Duress

A classic example of duress is a case where a robber holds a gun to the head of a driver and says "drive me to that bank which I am going to rob, or I will shoot you." If the driver does so, the driver has committed the *actus reus* and *mens rea* of robbery by knowingly assisting its commission. But he should be excused for his behavior because it was not the product of a meaningful choice. In most countries, the defense is invoked by an accused who claims he was threatened (or a member of his family was threatened) with immediate death or great bodily injury if he refused to participate in a crime; he had no lawful alternatives available, he reasonably believed the threat would be carried out, and he was not responsible for placing himself in a position where such a threat was likely.

Duress can be classified as a justification or an excuse depending upon the manner in which it is defined in each country. In France, it is properly considered a justification because proportionality is an additional requisite element. In other words duress is only available as a defense in France if the harm that is threatened if the accused does not comply is greater than the harm that the accused causes by doing what he has been ordered to do. On the other hand, in the United States duress is properly classified as an excuse because there is no strict requirement of proportionality. However lack of proportionality is nonetheless relevant as a factor that can be considered in deciding whether another legal requirement of duress in the United States has been met, namely, was the threat grave enough that a person of reasonable firmness would not have resisted it? In South Africa, there is no requirement of proportionality, only a requirement of reasonableness, but South Africa does not divide its exculpatory defenses into justifications and excuses (van der Merwe and du Plessis, 2004, Chapter 13). Conversely, many common law countries impose a proportionality requirement on the defense of duress yet inconsistently insist on referring to it as an excuse (Stuart, 2011). In these countries the defense of duress is very similar in character to the defense of necessity.

Provocation (Extreme Emotional Disturbance)

Provocation is a qualified or limited defense in two different respects. First, it is only a defense to one offense – murder. Provocation in respect to other offenses is no defense but it is a mitigating factor in sentencing (Stuart, 2011; Baker and Williams, 2012). Second, it does not result in a complete acquittal. Instead it reduces murder to manslaughter (or culpable homicide not amounting to murder) in common law countries and it reduces murder to 'mitigated murder' in continental countries. In both systems, the reduced offense provides for a lesser punishment than the punishment for murder. The rationale for provocation as a partial mitigating excuse is the belief that there are certain provocative incidents that are so strong that it is understandable (though not entirely excusable) that an ordinary person in those circumstances could temporarily lose his/her normal powers of self-control and lash out at the provoker with deadly force. Obviously the types of incidents that the law recognizes as sufficient to temporarily impair a person's power of self-control are premised on a society's dominant cultural beliefs at any given time. In England, provocation as

a defense was originally recognized if the killing occurred as a result of a sudden quarrel or if a husband caught his wife in an act of adultery. Slowly the circumstances where provocation was recognized expanded to any acts or words that might be sufficient to cause an ordinary person in circumstance similar to those of the accused to temporarily lose the normal degree of self-control expected of all of us.

The defense of provocation has received sustained criticism and has been the subject of several law reform efforts in the past 20 years (Ormerod, 2011; Bronitt and McSherry, 2010; Simester and Brookbanks, 2007). The major criticism of provocation is its disproportionate use in cases of males killing their wives, partners, or ex-partners in the context of jealousy, domestic discord, and abuse, or males killing other males based on a homophobic claim that the deceased provoked the attack by making an unwanted sexual advance on the accused (Warrick, 2011; Hemming, 2010). For example, in one Canadian study of 114 provocation cases in the 1990s, the accused were males in 107 of those cases and females in only seven cases; in just over one-half of those cases, the male accusers killed their intimate female partners or ex-partners. The claim of provocation succeeded in about 25% of these types of cases. The fact that provocation is raised in these types of cases leads to the criticism that the provocation defense is condoning male violence against women, at a time when it should be denouncing it in an uncompromising way.

The Australian State of Victoria significantly altered its provocation defense in 2005 to respond to criticisms about its use by males in family violence homicides and the relative ineffectiveness of the defenses of self-defense and provocation for women who kill their male partners as a defensive response after years of spousal abuse. The new legislation abolished the defense of provocation and, among other matters, enacted a new partial defense of 'excessive self-defense' that, if successful, results in a conviction of the lesser offense of defensive homicide. The new defense was designed to assist women who kill as a form of defensive response to (male) domestic violence in circumstances where the strictures of self-defense laws do not provide a defense. There is some controversy as to whether these reforms have been successful (Hemming, 2010).

New Zealand abolished the provocation defense in 2008. Provocation in New Zealand is now simply one of the mitigating factors a judge can take into account in sentencing the accused for murder. This reform option is viable in New Zealand because, unlike most other common law countries, New Zealand does not have a mandatory minimum sentence of life imprisonment for murder. In countries where murder is only punishable by life imprisonment, it is not possible to reduce that sentence regardless of the number or type of mitigating factors that exist (Simester and Brookbanks, 2007). In 2009, England abolished the defense of provocation and replaced it with a new defense called loss of control. Besides a change in name, the new law is an attempt to deal with some of the criticisms of England's former provocation defense (Ormerod, 2011). There is considerable debate as to whether the new law will result in much practical change. No doubt, in the years to come, other countries will continue to explore abolition or amendment of their provocation defense.

Conclusion

The above discussion of criminal liability and defenses demonstrates that the laws' definition and requisite elements are intended to reflect the circumstances in which a given society considers it fair and proper to assign blame and impose punishment for breach of its criminal laws. As society's views and values change, the legal requirements for a crime and a defense can and should change to match those new views and values. We have seen this process at work in the past 20–30 years in a number of areas including the defense of provocation, self-defense, necessity, and duress. In addition to changes in these defenses, there are other challenges to our articulation of defenses that are still developing. For example, to what extent should the law recognize an accused's particular cultural beliefs and values as relevant to self-defense, provocation, and necessity when the accused's beliefs are far different, or directly in conflict, with the majority's beliefs? And to what extent if any does the law's notion of voluntary conduct have to change as science continues to document how the ability to understand and control one's behavior are affected when an accused suffers from conditions such as fetal alcohol syndrome, attention-deficit disorder, and post-traumatic stress disorder? And as neuroscience continues its rapid progress in mapping the brain and measuring its activity, the law may need to abandon or alter some of its current assumptions about the nature of voluntary conduct, which underlies various defenses. These advances, and others not yet commonly understood, will continue to challenge society and its lawmakers in the creation of a fair and proper system of defenses for the imposition of criminal liability and punishment.

Criminal Procedure: Adversarial and Inquisitorial Legal Systems

Stephen C Thaman, Saint Louis University School of Law, St. Louis, MO, USA

Abstract

This article explains the historical development of the two main types of court procedures used in criminal, and to a lesser extent in civil, cases around the world. The adversarial system developed from the English jury trial and envisions a passive judge and an active role for the parties. The inquisitorial system sees the judge as active investigator of the truth and mistrusts lay participation. A third tradition, that of consensual resolution of cases and plea bargaining, grew not only out of the adversarial tradition but also, through its inducement of pleas of guilty, smacks of the inquisitorial tradition.

Introduction

There has always been a multiplicity of penal court procedures. The differences in how criminal wrongdoings were unraveled and settled often depended on the mode of their commission, the relationship between victim and perpetrator, and the seriousness of the offense. Three models for the resolution of conflicts arising from criminal wrongdoings have their roots in ancient procedures that have perhaps been common to all cultures. All were attempts to avoid the most primordial response to criminal wrongdoing: self-help and, in the case of homicide, blood revenge. All are relevant in understanding modern criminal procedure. These are (1) consensual semi-private resolution of the conflict through negotiations between victim or prosecutor and the accused, whereby 'consensual' refers to court procedures where the parties agree to a resolution without requiring a full trial; (2) adversarial resolution of the dispute in a public oral trial often held before a panel of lay judges (jury), whereby 'adversarial' means that evidence is produced by the parties (prosecution, defense) and the judge plays a neutral, more passive role; (3) inquisitorial investigation and decision of criminal cases, conducted in its heyday by state officials obligated to ascertain the truth (i.e., judges play a more active role in investigating the issues and ascertaining the truth and the parties play a more passive role).

All these procedural modes are found in varying mixtures in most modern penal procedures, albeit in different combinations, usually with one procedural mode dominating for cultural and historical reasons. They, and the principles derivative therefrom, inform contemporary discussions about criminal procedure reform in Asia, Latin America, the former Soviet Union, and other parts of the globe.

Criminal procedure consists in a sequence of acts or procedures conducted by officials aimed at determining whether crimes were committed, who committed them, and what their punishment, if any, should be. Criminal procedure reformers must assess the applicability of the three procedural modes to (1) the decision to arrest and commence a preliminary investigation (i.e., the procedure of investigating a crime, determining the identity of the perpetrator/s, and the legal qualification of the criminal act, before the case goes to a trial court); (2) the decision to detain the suspect pretrial; (3) the decision to charge a suspect with the commission of a crime; (4) the pretrial assessment of the sufficiency of evidence to allow the case to proceed to trial (preliminary hearing); (5) the decision as to guilt (the trial); and (6) decisions post-trial as to whether there was sufficient evidence to convict, whether errors were made that require a new trial, or whether a person acquitted may be retried.

Some Historical Watersheds in Criminal Procedure Reform

Early modes of consensual and adversarial resolution of criminal disputes predominated in Europe up until the late middle ages and the Renaissance, and exist in some communities in Africa, Asia, Latin America, and other parts of the world that still use customary law ('customary law' refers to procedures that were used before inquisitorial and adversarial procedures developed, such as ordeals, duels, and use of oaths). In both systems, the victim (or his or her tribe) made an accusation and the suspect-defendant responded. These early procedural systems were usually accusatorial in nature, that is, initiated by the victim as accuser. A variety of influences, both political and cultural, led to the development of a new system of criminal procedure on the European Continent, what is now called the inquisitorial procedure. Politically, the rise of the nation-state and absolute monarchy led to a politicization of criminal procedure, with the state replacing the victim as initiator of criminal proceedings. The vertical hierarchy of such systems was reflected in a vertical hierarchy of courts and a huge royal judiciary to administer it.

Culturally, the law was heavily influenced by the Roman Catholic canon law's inquisitorial procedures and formal rules of evidence and by the rediscovery of Roman law in the Italian universities. Judges began to see themselves (or to be seen) as truth seekers who, armed with the newly articulated Roman legal principles emerging from the Italian universities and with the rules of formal proof emanating from the Canon law, could achieve a quality of justice superior to that achieved by the irrational forms of procedure used by the Germanic tribes: ordeals, oath helpers, duels, and lay decision makers.

The judges were royal officials beholden to the monarch, with no fealty to the communities in which their judgments would resonate. Punishments were considerably more Draconian than in the early middle ages. Procedurally, the most radical new innovation was that of a formal preliminary investigation initiated *ex officio* and conducted by a judicial official who would examine the suspect and the witnesses,

conduct other investigative acts, and reduce all of the findings to writing. Because no accusation by the victim was required, the new procedure was called inquisitorial. The written results of this preliminary investigation were compiled in an investigative dossier, a file compiled by the investigative official during the preliminary investigation that contains all the evidence to be presented at trial. The investigative dossier became the exclusive record upon which the decision of guilt or innocence would be based. If, under the formal rules of evidence, enough indicia existed to constitute what one might today call probable cause or reasonable suspicion to believe that the suspect was guilty, then the investigating magistrate (the judge who carried out the preliminary investigation in early inquisitorial systems, and still does so in some countries such as France or Spain) could order the suspect to be tortured if he or she refused to be examined. There was no oral, public trial before a jury. Instead, the proceedings consisted of a secret written review of the findings of the investigating magistrate contained in the written investigative dossier. There was no right to counsel. There was no confrontation of defense and public prosecutor (or victim) as one knows it today, where the 'right to confrontation' denotes the right of the defendant to be present when the witnesses of the prosecution testify, and to question them.

Judges had no discretion to mitigate the harshness of the findings. Unlike the jury, which continued to function in England, inquisitorial judges could not reject the result mandated by the rules of evidence or acquit against the strictures of the law. The lay judges and litigious procedures that dominated in the earlier procedures were gradually eliminated in favor of a purely 'professional' and more administrative form of justice.

Yet the oral tradition persevered in England and to an extent in Scandinavia. Oral, public trials by a jury of 12 gradually replaced ordeals, duels, and the use of compurgators or oath helpers, friends of the accused or victim who would swear to their honesty and uprightness, by the thirteenth century. Verdicts had to be unanimous and the ensuing judgments were final, not allowing for any posttrial review. Other than a brief examining of witnesses and suspects for purposes of determining release on bail, there was no preliminary investigation. Victims or their lawyers brought the case and the accused defended himself, usually without a lawyer, until the eighteenth century.

With the advent of the French Revolution, these two systems confronted each other and led to a new mixed form of procedure on the European Continent. The French revolutionaries were inspired by Enlightenment criticism of the brutality of inquisitorial criminal procedure (invoking great thinkers like Beccaria, Montesequieu, and Voltaire) and were influenced by the antiauthoritarian credentials of the English jury trial (provided by the notorious acquittals of William Penn and others dissidents against the instructions of royal judges). As a result, they introduced to France the public, oral English jury system, eventually grafting it on to the secret, written, inquisitorial preliminary investigation.

The French Declaration of the Rights of Man in 1789 and the American Bill of Rights of 1791 were products of the first great human rights revolution that impacted criminal procedure, leading to its gradual humanization by protecting the criminal suspect from the arbitrary and pitiless power of the state. The American Bill of Rights proclaimed the protection against cruel and unusual punishments and unreasonable searches and seizures, the privilege against self-incrimination, and a host of trial rights, including the right to counsel, to subpoena witnesses for the defense, to cross-examine or confront the witnesses of the prosecution, and the right to a speedy, public trial by a jury of the defendant's peers. All these rights were meant to protect against overreaching by the state, either by securing important rights of suspects during the gathering of evidence, or by assuring that the defendant would not be tried on the basis of written evidence prepared by the state in secret, without input or checking by the defendant through cross-examination. The presumption of innocence was proclaimed by the French Declaration and was held to be implicit in the due process rights granted by the American Bill of Rights.

Although jury verdicts in France were final, like in England, French juries were asked to answer a list of specific questions related to the elements of the charged crime(s) and the guilt of the defendant(s) contained in a special verdict, which sometimes contained dozens – if not hundreds – of questions. The inquisitorial, written tradition on the European Continent preferred reasoned judgments; a particularized special verdict was intended to make the jury's reasoning process clear and better facilitate appellate review of their verdicts. Often, the professional judges would evaluate the substance of the jury's factual answers and pronounce judgment, thus limiting the autonomy of the jury's finding of guilt. The French jury model, in which a jury of twelve was presided over by three professional judges, and in which only a majority verdict was required, was adopted by nearly all European countries in the nineteenth century. In Germany, a mixed court, composed of one professional judge and two assessors, in which lay and professional judges collegially decide questions of fact, law, guilt, and sentence, developed in the mid-nineteenth century for the trial of lesser offenses (the term 'mixed court' in general refers to courts made up of one or more professional judges and a group of lay judges who deliberate together and together decide all issues of fact, law, guilt, and sentence).

The continental European mixed system and the Anglo-American system of adversarial jury trial were spread through colonization, imperialism, and systematic borrowings into Asia, Africa, and Latin America. Ironically, many of the Latin American countries that liberated themselves from Spanish and (in the case of Brazil) Portuguese rule in the early nineteenth century kept the purely written inquisitorial procedures conducted exclusively by professional judges and rejected the reforms that swept the European continent. Only Brazil, Panama, Nicaragua, and El Salvador introduced trial by jury, but these nations largely limited the jury's role to reading the contents of the inquisitorially prepared investigative dossier.

Jury courts were always controversial on the European continent and many jurists sought to abolish them or to convert them into mixed courts. This was finally accomplished by the totalitarian regimes of the first half of the twentieth century. Juries vanished in many countries, replaced by mixed courts or purely professional panels, in 1917 in Russia, in 1931 in Italy, in 1939 in Spain, and in 1941 in Vichy France. In 1943 in Japan, jury trials, which had been introduced in 1928, were suspended.

Jury trial was eliminated in Germany in favor of the mixed court before the rise of Nazism to power, by decree in 1924.

After the defeat of Nazism and Fascism in World War II, Italy, France, and Germany did not return to the classic jury, preferring the mixed court. The mixed court cemented the dominance of the professional bench over its lay component by enabling the judge to personally influence the lay judges in how they decided the question of guilt. It also was more consistent with the necessity of giving reasoned judgments in all criminal cases.

The horrors of World War II and the Holocaust and the crimes of the totalitarian regimes led to a new era of human rights in the latter half of the twentieth century, with the adoption of the Universal Declaration of Human Rights, the International Covenant for Civil and Political Rights, and the European, American, and African Conventions on Human Rights. The European Court of Human Rights has greatly influenced the reform of European criminal procedure through its interpretations of the European Convention. In the wake of this revolution, and with the postwar democratization of Germany, Italy, France, and Japan and of Spain after Franco's death, many European countries began to systematically eliminate many of the negative vestiges of the old inquisitorial systems that had survived since the French Revolution.

A distinct shift toward adversary and consensual procedures has been noticeable since the late 1980s. The 1988 Italian Code of Criminal Procedure introduced an adversarial trial system and several forms of consensual resolution of the guilt issues; it did not, however, adopt trial by jury, because the Italian Constitution requires that judges give reasons for criminal judgments, and the authors of the Constitution felt that juries were unable to give such reasons. Russia, on the other hand, reintroduced adversary procedure and the jury in 1993 and a form of consensual resolution of cases in 2001. The majority of the former Soviet Republics have followed the Russian model, although only Georgia has introduced trial by jury. Azerbaijan and Kyrgyzstan have, however, passed laws aimed at its eventual introduction.

Spain strengthened the adversarial nature of its trial system by introducing trial by jury in 1995. It then took a daring step by requiring its juries, consisting of nine citizens needing seven votes to convict, to give concise reasons for their answers to the questions contained in the special verdicts. This innovation proved to be critical for the whole continent; the European Court of Human Rights, in the case of *Taxquet v. Belgium* (2009), overturned the conviction of a man for murder of a Belgian politician because the jury's verdict did not give any indication of why they chose to convict. The Court made clear that the decision was not calling into question the Anglo-Saxon jury system as such, as long as clear judicial instructions to the jury made verdicts understandable to the public and to the defendant. However, the case did induce Belgium to require its juries in the future to provide reasons for their verdicts.

The Adversarialization of the Inquisitorial Preliminary Investigation

The centerpiece of inquisitorial procedure was always the preliminary investigation, traditionally carried on by an investigating magistrate who was usually a member of the judiciary. Even after the inquisitorial systems reformed to include an oral trial by jury, most systems allowed the trial court to read the reports, including those of forensic experts, contained in the investigative dossier. This constituted a prepackaging of evidence by law enforcement agencies with no opportunity for the defense to see or confront the witnesses. Some countries allowed a minimal amount of participation by counsel. For instance, since 1897, France has allowed counsel to participate during judicial interrogations of the suspect, but this was of little help to the suspect because his or her interrogation by the police was always conducted in secret, with no right to counsel.

Substantial changes in the inquisitorial preliminary investigation only occurred after the second human rights revolution following World War II. The role of a judicial official as investigator began to be questioned, for how can a judge, who is following his or her particular theory of guilt in a case, be independent, neutral, and judicial when issuing arrest, search, or wiretapping warrants? Since it was the police who, in reality, did the lion's share of actual criminal investigation, and since it was the prosecutor who was responsible in most countries for preferring the charges, it was decided to put the prosecutor in charge of the preliminary investigation and to reduce the judicial role to that of a liberty or control judge, a neutral arbiter of invasions of human rights (authorizations of arrests, seizures, searches, and wiretaps) who could also preside over interrogations. This step was taken in Germany in 1974, in Italy in 1988, in Venezuela and other Latin American countries in the 1990s. The prosecutor still maintained the inquisitorial control of the investigation and determined which witnesses and experts would testify in the case. In Spain, new legislation, such as the 1995 jury law, has transformed the investigating magistrate into a more neutral pretrial judge by allowing him or her to investigate only in response to a request by either the public or private prosecutor (victim) or the defense.

In the Soviet Union and formerly socialist Eastern Europe, it was the public prosecutor who not only generally directed the preliminary investigation (which was in the hands of an investigator provided by the Ministry of the Interior) but also authorized all invasions of protected human rights of suspects. Former socialist countries that have since ratified the European Convention of Human Rights have gradually introduced new legislation requiring judges to perform these important functions, and the ex-Soviet republics of Central Asia have by and large followed suit.

Protection of suspects from secret, custodial, counselless interrogations was greatly influenced worldwide by the famous decision of the US Supreme Court in *Miranda v. Arizona*, 384 U.S. 436 (1966). Today, most of the formerly inquisitorial systems of continental Europe, the former Soviet Union, Latin America, and South Korea require law enforcement officials to advise suspects of their right to remain silent and their right to counsel before being questioned, and many new codes of criminal procedure, such as those of Italy (1988), Venezuela (1998), and even the Kyrgyz Republic (1999) require counsel to be present during all interrogations. (This is a requirement that extends beyond what US law requires.) This trend has also been substantially strengthened by a decision of the European Court of Human Rights, *Salduz v. Turkey* (2009), which has

recognized a firm right to counsel during the preliminary investigation and especially during police interrogations.

Increased recognition of the right to confront witnesses, guaranteed by Art. 6(3)d of the European Convention of Human Rights, has led formerly inquisitorial countries to require, where possible, the presence of the defendant and/or defense counsel during the examination of prosecution witnesses during the preliminary investigation. The European Court of Human Rights has repeatedly condemned the use of written statements where they are the sole or main evidence of guilt in criminal cases, if the defendant had no chance pretrial to confront and examine the witness. The 1988 Italian Code requires the prosecutor to initiate a hearing to preserve witness testimony in cases where there is fear the witness may not be available for trial. At this hearing, the defendant and victim have the right to be present and to examine the witness; failure to honor this right means the statement cannot be admitted at trial. Similar provisions exist in the 1995 Spanish Jury Law and in new Latin American codes of criminal procedure. Thus, procedure in formerly inquisitorial countries is approximating that in the United States, where the inadmissibility of pretrial, out of court, unconfronted statements was strengthened following the decision of the US Supreme Court in *Crawford v. Washington*, 541 U.S. 36 (2004).

In Italy and in cases subject to Spain's new jury law, the preliminary investigation is not supposed to be the stage for preparing evidence to be used at the trial, but only for determining whether sufficient probable cause exists to charge the suspect. Any evidence that could be presented at trial and is not required for a showing of probable cause need not be taken during the preliminary investigation. In this sense, the preliminary investigation tends to resemble the American grand jury or preliminary hearing. In fact, the investigative dossier is, in principle, not to be used during the trial as a source of evidence. A special trial dossier is compiled, including the accusatory pleading and any evidence that has been properly preserved for trial, guaranteeing defense rights of confrontation as noted above.

Some formerly inquisitorial countries have gone a step further, however, by allowing parallel defense investigations as exist in the United States. The 1988 Italian Code provides for defense gathering of evidence in preparation for the trial phase, while amendments in 1999 provide for detailed procedures to regulate the gathering of this evidence and its eventual unification with the prosecution evidence in a common investigative file. The Russian code of 2001 also allows defense investigations.

The Decline of the Inquisitorial Trial Judge

The trial judge in the nineteenth-century mixed systems on the European continent acted like the quintessential investigator. After reviewing the investigative dossier, the judge decided which witnesses would be called, and examined the witnesses at trial. Since the judge had reviewed the investigative dossier and had it at hand, he or she was aware of the inculpatory premises put forward by the investigating magistrate and usually adopted them, for he or she had to decide pretrial whether there was sufficient evidence to set the case for trial. It stretches the imagination to believe that such a trial judge actually entertained a presumption of the innocence of the defendant in such a procedure. Predictably, the written judgment would often closely follow the language of the written accusatory pleading.

On top of that, the defendant was called to answer the charges at the beginning of the trial in front of the jury and/or judge and asked to give a statement before any other witnesses were called or evidence presented, seemingly belying the fact that the burden was on the state to prove the charges. The judge then examined the defendant, using the materials in the dossier to guide him or her in the 'search for the truth'. The prosecutor and defense counsel would be able to submit questions (often only in writing to the presiding judge) to supplement the examination of the judge. If witnesses did not appear, the presiding judge would merely read the statements they had made to the investigating magistrate during the preliminary investigation.

As long as European systems had juries, the trial judge was not a judge of the facts, so the judge's lack of neutrality did not necessarily directly affect the outcome of the case. But when most European systems and Japan eliminated the jury in favor of professional or mixed panels, the same judge who 'investigated' the case at trial using his or her inquisitorial skills (and who may have adopted the findings of the investigating magistrate) also decided the case. This practice appears to violate the presumption of innocence.

This system, which still largely exists in France, Germany, the Netherlands, Belgium, and other countries, is gradually being replaced by the adversarial model, where prosecution and defense are responsible for preparing and presenting the evidence and witnesses, including expert witnesses. In this model, the judge assumes a more passive role, deciding questions of admissibility of evidence and making sure the parties have 'equality of arms' in presenting their cases.

In 1998, Italy was the first to eliminate the preliminary investigation dossier from the courtroom. Spain followed suit in its 1995 jury law, as did Venezuela in 1998. Italy also eliminated the presiding judge's duty to determine the truth, which was important because, unlike in Spain and Russia, Italy did not return to the jury trial, which means the judge remains a trier of fact. Already in 1992, the Russian Constitution was amended to provide for adversarial procedure and trial by jury. Jury trials began in Russia in 1993; since the 2001 code of criminal procedure was enacted, they now exist throughout the country.

Since 1990, most Spanish-speaking Latin American countries have moved away from the old pre-Napoleonic inquisitorial systems to an accusatorial-adversarial system. Latin American countries, however, have by and large kept their professional judges, although the Argentinean province of Cordoba, Venezuela, and Bolivia have introduced mixed courts and the Province of Buenos Aires, in 2013, passed legislation to introduce jury trial. El Salvador and Nicaragua have modernized their old inquisitorial jury systems within new adversarial codes of criminal procedure. Japan and South Korea also introduced new mixed court systems in 2009. The Soviet mixed court, which replaced the Russian jury court in 1917, was adopted in nearly all countries in the socialist bloc following World War II; many of these countries, whether or not they

have become democracies, continue to use a court composed of one professional judge and two lay assessors in criminal cases (Poland, Czech Republic, Hungary, China, Vietnam, among others).

The 'search for truth' at all costs during the criminal trial has also come under attack, following growing recognition that evidence gathered in violation of the human rights of criminal suspects (usually violations of the right of privacy, the right to human dignity, or the privilege against self-incrimination) should not be used in the criminal trial even if it is otherwise relevant and credible evidence of guilt. The United States took this step in 1961 with the landmark decision of *Mapp v. Ohio*, 367 U.S. 643 (1961), which recognized an exclusionary rule in relation to illegally gathered evidence (an 'exclusionary rule' prevents the use of evidence, even if relevant and reliable, which was seized in violation of important constitutional rights of the defendant). In most Western countries, however, the search for truth still prevails because the courts take a very cautious approach to exclusion of evidence, especially when it is very credible physical evidence. They engage in an elaborate balancing process that in the end usually leads to exclusion of evidence only when the violations have been egregious, such as the case of torture (Germany, England and Wales, Canada, Australia, and New Zealand). In Italy and Spain, legislatures have passed laws that require exclusion of such evidence, yet only the Spanish courts have enforced this law with any vigor. The Russian Constitution of 1993 mandates exclusion of illegally gathered evidence, as do most of the new post-Soviet constitutions and many new Latin American constitutions.

The Eclipse of Adversarial and Inquisitorial Procedure?

Although adversarial principles appear to have triumphed over their inquisitorial counterparts in modern criminal procedure reforms, criminal procedure today is increasingly marked by avoidance of the full trial, through plea bargaining or other consensual procedures. Plea bargaining is a type of consensual procedure in criminal cases where the defendant agrees to plead guilty to a charge and punishment that are arrived at through negotiations between prosecution and defense, and where not trial takes place. In the United States, over 95% of all cases are decided by guilty pleas, which are often prompted by the threat of Draconian sentences if the defendant goes to trial and loses. Since Italy enacted its code of criminal procedure of 1988, introducing several types of consensual avoidance of a full trial that were similar to plea bargaining, nearly all European countries have followed suit, and today guilty pleas or stipulations are rapidly replacing trial as the dominant mode of resolving criminal cases. Although the agreement between the parties smacks of adversarial procedure, the pressure placed on the defendant to admit guilt reminds one of old inquisitorial practices of inducing confessions.

Although in the United States there are few restrictions on the sorts of cases that can be bargained (one can even strike bargains in death penalty cases), most countries use procedures similar to guilty pleas only for lesser charges. Where the punishment consists only of a fine or a suspended jail sentence, many countries allow the prosecutor to issue a 'penal order,' which contains a stipulated charge and sentence, and the defendant has a period of time, say 2 weeks, to accept the order or to request a trial. Italy, France, Russia, and several former Soviet republics have introduced a system whereby a defendant who is facing less than 10 years imprisonment (Russia), or 5 years (France and Italy), agrees not to contest the charges, and in exchange receives a one-third discount on what would have been the sentence. An increasing number of countries are also allowing 'cooperation agreements' in very serious cases, which can lead to large discounts in sentencing, or even dismissal, if a suspect or defendant cooperates with the prosecution to help convict a more serious criminal. Russia took this step in 2009.

Notably, these abbreviated and consensual procedures induce defendants to give up the broad protective rights they have only earned after centuries of struggle, and to accept guilt without a trial in order to avoid the threat of a higher punishment. Because of plea bargaining, trial by jury, perhaps the most protective procedure, is virtually disappearing in the United States, while jury trials in countries that have only recently returned to them, such as Russia or Georgia, are becoming few and far between.

Criminology: Development and Current Status of the Discipline

Charles F Wellford, University of Maryland, College Park, MD, USA

Abstract

The development of criminology as a separate academic and research discipline is traced from the late 1700s to the present. The major conclusions for criminology are (1) causal theories have not proven to be very robust and powerful. Future theory development will require the development of interdisciplinary theory. (2) Criminology has not experienced significant growth in the last 20 years. The needed expansion of the field will require a new federal effort to build the infrastructure for crime and justice research. (3) The changing nature of crime and scientific methods in criminology, the internationalization of crime, and the demand for more evidence-based policies and practices present new challenges for the discipline of criminology.

Introduction

The goal of this article is to provide an analysis of the development and current status of the discipline of criminology. Criminology is a behavioral and social science. It is not the investigation of specific crimes. Too often the public, under the influence of the media, confuse criminology as a science of behavior, and criminalistics and forensic science as they are applied in the investigation and processing of criminal cases. Here we consider criminology in the sense defined by Sutherland, one of the pioneers in establishing the science of criminology. Sutherland (1934) defined criminology as the scientific study of the making of law, the breaking of law, and the reaction of society to law breaking. Criminology is one of the fastest growing social sciences and at many universities is one of the largest programs in terms of number of majors (between 1970 and today, it is estimated that enrollment in criminology programs at universities in the United States have increased by a factor of 1000, partly because of the rapid growth in the number of such programs).

How we understand the past is often influenced by how we see the present. Today criminology finds itself defined by three major themes: the steady movement toward a more rigorous science; a commitment to the development of rigorously tested theories of crime and criminal behavior; and the establishment of a demand for evidence-based crime control and justice policies and practices. However, the history of the discipline is not as unified. Two, in part, conflicting approaches define the foundation of criminology. The next section describes those approaches and their influence today.

Two Points of Departure for the Beginning of Criminology

The Classical School of Criminology

This pillar of criminology begins with the work on an Italian lawyer, Cesare Beccaria. Working with a small group of his friends and fellow lawyers, Beccaria published what was to become one of the most important works for criminology, and more importantly for criminal justice reform. Published in 1764 this book would become one of the most influential legal treatises of the eighteenth century (*Essays on Crime and Punishment* (hereinafter referred to as Essays)). (He was the primary author but contemporary scholarship suggests that others were intimately involved in the development and writing of the book. While that is not critical for this article, you can find a discussion of this in the forward to the Paolucci edition (1963).) Influenced by the Enlightenment philosophers, Beccaria sought to reform the criminal justice system to make it more humane and fair. He argued for punishments other than corporal punishment and death by embedding punishment in an enlightened legal system. Within 10 years of its publication the book was translated into all European languages; Beccaria was celebrated as a profound new legal thinker; and, the work influenced the governments of numerous countries including England and the United States. As early as 1775 John Adams referenced this work in his justification for accepting the unpopular and politically dangerous task of defending the British soldiers who fired on the citizens of Boston who charged the arms depot atop Bunker Hill. Adams (quoted in McCullough, 2001) in explaining this decision quoted the following from Beccaria:

> If, by supporting the rights of mankind, and the invincible truth, I shall contribute to save from the agonies of death one unfortunate victim of tyranny, or of ignorance, equally fatal, his blessing and years of transport will be sufficient consolation to me for the contempt of all mankind.

Beccaria offered four central tenets of a new approach to criminal justice. First, he rejected the then dominant idea that crime represented a moral failure. With religion as the source of power in society it was understood that personal and social failures resulted from a falling from grace. Beccaria accepted the notion from Bentham (1789) that behavior was always a choice and that choices were determined by a 'moral calculus.' Crime resulted when the rewards of crime outweighed the costs (pains) resulting from the commission of crime. Second, Beccaria argued that because crime was a choice influenced by rewards and punishments, punishments need be just severe enough to offset the rewards of the crime. At a time when the death penalty and corporal punishment were common, he argued for a more

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45052-X

rational system of punishments, one in which there would be no death penalty. Third, Beccaria called for the application of science to determining the exact level of punishment for each crime. These punishments were to be determined with 'geometric precision.' Finally, Beccaria understood that any science of punishment could be seen as challenging the established powers and their interests. So he argued that his new law system was consistent with the teachings of the church. These central ideas formed the basis for criminal justice systems in the emerging western democracies and an agenda for criminology that focused on rationalizing the criminal justice system.

In the second foundation for criminology we see a very different set of assumptions and foci. This approach pays little attention to the criminal justice system and the focus is almost exclusively on the causes of crime.

The Causes of Crime

Cesare Lombroso was an Italian physician, who worked in local prisons. Apparently heavily influenced by the recently published work on Darwin on evolution, Lombroso considered how criminality could be explained within an evolutionary perspective. Like Beccaria, his contribution was to take an emerging world view and apply it to the problem of crime. As he worked with criminals he began to notice physical characteristics that suggested to him that they had not fully developed as humans – their criminality was a result of this lack of development. This idea was summarized with numerous examples in his book *Criminal Man* published in 1876. This brief book (approximately 250 pages) argued that crime was caused and that it was caused by a biological developmental anomaly. Criminals did not choose to commit crime; their behavior was caused by factors beyond their control. Until the beginning of the twentieth century the idea that biology was destiny for criminals became increasingly popular. Not until Charles Goring tested this approach by conducting a statistical analysis of the physical characteristics of criminals and noncriminals did students of crime begin to explore other approaches to explaining crime (Goring, 1913). Still, Lombroso was successful in directing the study of crime to a new set of questions: what causes crime and what does our knowledge of crime indicate for a system of crime prevention and control – the second approach influencing criminology as it emerged as a separate discipline. (Lombroso gradually began to understand that factors other than biology influenced crime. By the time he wrote the fifth edition of his book it had grown to 1903 pages and identified hundreds of causes of crime. Still he is most remembered for his emphasis on the biology of crime. For a detailed discussion of this period in criminology see Chapters 3 and 4 in Vold (1979).)

In fact, by the time this work was published Lombroso had published the fifth edition of his book, each one getting longer and noting other possible explanations of crime (the fifth edition had grown to 1903 pages and listed hundreds of causes of crime). (This in part explains Lombroso's new appreciation in contemporary biological criminology (DeLisi, 2013).) In 1885, Rafaele Garofalo (a student of Lombroso) introduced the word criminology in his influential book by the same name (*Criminology*). It would be over 50 years from then before a professional society devoted to crime and justice would emerge, and separate academic departments of criminology would be created in American universities. As it emerged some 75 years ago as a new social and behavioral science, it stood on two foundations: the science of criminal justice and the science of criminal behavior. In very important ways they continue to be the two, sometimes conflicting, foci on contemporary criminology.

Explaining Crime and Criminal Behavior

Even though Beccaria wrote first, the emergence of a science of criminology started with the focus on causes of crime introduced by Lombroso. It was not until the mid-twentieth century when criminology began to pay scientific attention to testing and improving the criminal justice system. While criminological theory has been less cumulative than you would expect in an emerging science, it has accumulated. The path of theories of crime has moved through four distinct forms of theory development: single factor reductionism; systemic reductionism; multidisciplinary theories; and interdisciplinary theory. (These are themes that seem more prominent at different points in time. This is not to imply they have occurred in a liner fashion. In fact, all approaches exist today.) Today, interdisciplinary theory stands as the dominant model for explaining crime (and other human behaviors). It is also the case that while Lombroso focused on why individuals commit crimes, crime theories are also used to explain why crimes occur at different levels in different sections of the population, geographical areas, and/or times. Being clear about what the theory is intended to explain is vital to understanding its strengths and weaknesses (for a more detailed discussion *see* Sociology of Crime). In addition, theories tend to not distinguish the kind of crime being explained, as if one theory could explain homicide and use of controlled substances. (See articles in this volume on specific crimes for more details on their distribution and causes.)

Single Factor Reductionism

In an effort to explain crime in the simplest way, some have offered a single factor or idea to explain all crime. Following Lombroso numerous authors offered explanations of criminal behavior: 'feeblemindedness' and family transmission, poverty, single parent families, abortion, lead paint – the list could go on and on. The most positive observation on these approaches is that they identify characteristics of crime that a theory should address. More to our point, these approaches tend to distract criminology into research to test ideas that even Lombroso understood were limited as he expanded his notion of what could be involved in causing crime. Still these approaches have the advantage of simplicity, and they have clear policy implications. By the end of the first quarter of the twentieth century it was understood that no single factor could explain criminal behavior and crime rates. (This approach continues today in some public and political discourse. Too frequently we hear that crime is caused by 'welfare moms,' lead paint, unemployment, and a variety of other factors. Criminologists can usually respond yes, but that is just one of a myriad of characteristics that may cause crime and the problem is we do not know which is most important and how these many factors interact. This type of response reinforces the idea held by some

that criminologists do not know much about the causes of crime.) However, just as difficult as saying a single dimension explains crime is to say everything causes crime. In the search for some way to limit and organize explanations the period of systemic reductionism emerged.

By systemic reductionism I mean the approach that still dominates the field, the assertion that one discipline can explain crime. Hence, in many recent introductory texts there are separate chapters or sections on biological theories, psychological theories, sociological theories, and cultural theories. Since criminology emerged in the United States in departments of Sociology, that approach dominated theories of crimes. Along with this focus, came a focus on crime rate variation as opposed to Lombroso's focus on individuals who committed crime. Most of contemporary criminological theory contains a strong if not exclusive sociological core. The works of Sutherland (1934), Shaw and McKay (1942), Merton, Schur (1971), and those who tested and elaborated their works form the core of much of contemporary theory in criminology.

Multidisciplinary Approaches

It took a husband and wife team trained in education, social work, law, and social ethics (Sheldon and Eleanor Glueck), and heavily influenced by a psychiatrist brother (Bernard Glueck) to challenge the notion of systemic reductionism. For the Gluecks it was obvious that the work of psychiatry, biology, and psychology was as important as sociology in understanding all human behavior including crime. They set out to understand all of the factors that distinguished criminals and delinquents for those who did not engage in those behaviors. In one of the clearest statements of the problem of systemic reductionism they stated:

> It is common knowledge that the great majority of children growing up in urban slums do not become delinquents despite the depravations of a vicious environment, despite the fact that they and their parents have not had access to fruitful economic opportunities, despite the fact that they are swimming around in the same antisocial subculture in which delinquents and gang members are said to thrive. Why?
>
> Glueck and Glueck, 1968

Sociological approaches might be appropriate to explain the variation in rates across class levels, but it could not explain why similarly situated individuals did or did not commit crime. To address that question, the Gluecks turned to all of the social and behavioral sciences as they were practiced in the 1930s to the 1970s. In a series of retrospective longitudinal studies they sought to determine how to distinguish those who did and did not violate the law by measuring every dimension of large samples regardless of the discipline the distinguishing factor might be drawn from. Unfortunately, this approach offers little basis for theory development or explanation. It ends up being an approach to prediction not explanation. So in their best-known work, *Unraveling Juvenile Delinquency* (1950) and its elaboration *Delinquents and Nondelinquents in Perspective* (1968), the Gluecks did offer a theory of delinquency but rather a 'social prediction' scale that would achieve their goal of distinguishing law violators from others.

Of course, we now understand that multidisciplinary approaches are not theories. They are the search for all of the factors that need to be addressed by theory. There is always another factor to consider. There is no logical end to the effort. The only end is the explanation of all variation. In that sense, it is more like what today we call data mining than it is explanation. However, the demonstration that there is more to explanation than sociology ushered in the current focus for explanation in criminology – interdisciplinary theory.

Interdisciplinary Explantations

Although the growth of criminology was stimulated by federal programs aimed at improving justice, as it emerged as a separate field of study it defined itself as interdisciplinary – not multidisciplinary. Without this understanding of its central characteristic there would be no need for a separate discipline. The study of crime and justice could continue in the various traditional, social, and behavioral sciences. While many academic criminologists continue to be located in the more traditional departments, the field of criminology understands itself to be interdisciplinary. So when the American Society of Criminology emerged as a scientific, scholarly organization, it placed an interdisciplinary perspective as being central to criminology. This is best exemplified in *Criminology*, the official journal of the American Society of Criminology, which has its subtitle *An Interdisciplinary Journal*.

As noted earlier this does mean that all theory in criminology is now interdisciplinary. In fact, earlier theories continue to dominate, but increasingly, we and others understand their limits. A recent article, by Weisburd and Piquero (2008), is an indicator of the problem. They perform an analysis of all recent tests of contemporary criminological theory. They empirically demonstrate that:

> The overall level of variance explained is often very low with 80–90% unexplained. There has been no improvement over time.

Interdisciplinary theory is difficult to define and more difficult to achieve. We know it must contain more than one discipline, and that the contributions from each discipline must be independent but related (for a complete discussion, see Wellford, 1989). An example of contemporary interdisciplinary theories is the work of Terrie Moffitt (2001). This theory includes all disciplinary levels, recognizes the changing nature of criminal behavior and its causes over time, and seeks to identify different patterns of crime to explain. For Moffitt (2001), there are two patterns of antisocial behavior: life course persistent where offenders start early and maintain their involvement in antisocial behavior throughout the life course; and, adolescent-limited whose antisocial behavior emerges and ends during that period of the life course. Moffitt observes that the persistent ones result from "childhood neuropsychological problems interacting cumulatively with their criminogenic environments producing a pathological personality." With the adolescent-limited pattern "a contemporary maturity gap encourages teens to mimic antisocial behavior in ways that are normative and adjustive." For Moffitt, explanation of these patterns included biology, psychology, and social levels of explanation. The history and

research in criminology on causes of crime point to the importance of interdisciplinary models; the contention that criminology is a separate and distinct discipline rests on a recognition that interdisciplinary theory is at the core of criminology.

The Beccarian Revival

Criminology returned to a focus on the justice system in the 1950s and 1960s. Studies on arrest, prosecution, and imprisonment began to emerge in this period that pointed to clear problems in almost every aspect of the criminal and juvenile justice systems. Not only were they failing to prevent and control crime, they were found to be disparate in their application. They were neither effective nor fair. When the urban riots of the 1960s and law enforcements reaction to the aroused national concern, a Presidential Commission was established to consider how to improve the system. The report of that commission (1967), titled the *Challenge of Crime in a Free Society*, while acknowledging the need for better understanding of the causes of crime, placed greater emphasis on the important of reforming criminal and juvenile justice. At the same time the report acknowledged how little we knew about these systems and the importance of research to gain the understanding that could support reform. The result was a substantial new effort by the federal government to support research and grow the research infrastructure to conduct research on crime and justice. The development of criminology was directly stimulated by this call for research to reform justice in America. Since the actions taken to implement the recommendations of the President's Commission, criminology has emerged as a new field at most universities in the United States, a source of major funding for the social and behavioral sciences, and a source of findings and ideas that have profoundly influenced criminal and juvenile justice here and around the world.

Few major initiatives in criminal law and criminal justice during this period have been developed without significant criminological involvement. Hot spots policing (Sherman et al., 1989), problem oriented policing (Goldstein, 1990), crime mapping and analysis (Harries, 1974), sentencing guidelines, specialized courts, sex offender programing, effective models of rehabilitation, reentry programs, problems of eyewitness identifications, procedures for police lineups and interrogations, the role of DNA in courts and policing – I could go on and on (*see* Criminal Justice, Sociology of for more a fuller discussion). The point is that criminology is making a difference. As we note in the following section, this has culminated in a new emphasis throughout the justice system – evidence-based policy and practice.

Contemporary Issues in Criminology

Criminology today confronts many challenges and issues. In this section, we discuss some of the most important issues facing the field today. Of course, one is the further development of interdisciplinary theory of crime discussed above. We do not repeat that discussion but note its centrality to the further development of criminology as a discipline. Advances in interdisciplinary theory and the resolution of the following issues will define how well criminology does in the future.

Growth of the Discipline

While undergraduate enrollments in criminology programs have surged in recent years, the number of universities with criminology departments offering advanced degrees has hardly grown in the last 15 years (during the last rankings of graduate education in the United States by the National Research Council there were still not enough doctoral programs to warrant the inclusion of criminology in the rankings). Few elite universities offer degrees in criminology. Membership in criminological professional societies is stagnating. Federal funding for crime and justice research has actually decreased as a percentage of federal spending. Today, some of the most important advances in criminology come from researchers in other disciplines and in the nonuniversity research community. This is occurring as the demand for criminological research is increasing. It will fall to the leaders of the leading criminological professional societies to generate support for a new period of federal funding for expanding the infrastructure for criminological research. Just as they have done in many other research and applied fields, the federal government must lead the way in the expansion and improvement of criminological higher education.

The Measurement of Crime

In the late 1920s a group of police officials and academics created, with no empirical research, an index of crime that exists to essentially unchanged. Managed by the Federal Bureau of Investigation (FBI), this voluntary but hopefully uniform system assumes that a count of homicides, serious sexual and other assaults, robbery, burglary, larcenies where the loss is above $500, and auto theft can provide an index to changes in all crime. Only in a country with as weak a statistical system to measure crime as the United States would take seriously this index of crime as a serious measure. In recognition of this fact, in 1980 a new system was proposed (the National Incident Based Reporting System) which has not been adopted by even a majority of jurisdictions in the United States. In addition, in the over 80 years since the creation of the FBI's uniform crime reporting system crime itself has changed. Cybercrime, Internet fraud, business-related crimes, etc., were unheard of in 1929. These crimes can be construed as crimes in the FBI index of crime (i.e., Internet fraud is a form of theft), however, most are not reported to police (in fact are not even known to the victim). In recognition of these changes, the Bureau of Justice Statistics has recently launched an effort to reconsider the kinds of crimes counted in an index and the mechanisms that would be used to count those crimes (NCS-X, 2012). Developing new and more robust measures of crime and their characteristics is essential to the future of criminology as a science of crime and justice. These ideas are more fully developed in the article on 'Crime Trends and Debates' in this Encyclopedia.

Changes in the Science of Criminology

In two recent reports from the National Academies of Science (NAS) challenged the notion that important criminological questions can be answered with what has been a central component of the criminological toolbox, statistical modeling of existing data. In consideration of the research on the impact

of right to carry laws on crime, the NAS committee on firearms (National Research Council, 2005) "concluded that with the current evidence it is not possible to determine that there is a causal link between the passage of right-to-carry laws and crime rates" (p. 150). In an Appendix to that report, Joel Horowitz explained that "In summary, the problems posed by high-dimensional estimation, misspecified models, and lack of knowledge of the correct set of explanatory variables seem insurmountable with observational data" (p. 308). Similarly, in an NAS report on the death penalty (NRC, 2012) the committee reached the conclusion that the research on the death penalty was so flawed (by characteristics similar to those discussed by Horowitz) that it could not be determined if the death penalty had any effect on crime rates. Research using observational data, with weak or no theory, and models and specifications that are highly dimensional are not likely to produce useful knowledge. Unfortunately this characterizes much criminological research (*see* Quantitative Methods and Crime).

It may be that two recent developments are in reaction to the problems noted above. First is the increased emphasis on experimentation as the preferred method for causal research. Of course, randomized controlled trials have long been understood to be the gold standard for research. However, in criminology the use of experiments has been rare until the last 20 years. Now there is a *Journal of Experimental Criminology* and a section of the American Society of Criminology devoted to experimental research. While focused on the testing of intervention effects, the introduction of experimentation as a focus of criminology has contributed to the challenge to more traditional research that relies on existing data and the use of modeling to account for problems in the data. The second development is the application to data mining with a corresponding shift from causal to predictive understanding (e.g., see Berk, 2009; Brantingham, 2011). This approach seeks only to predict outcomes and thus overcome the limitations of modeling of existing data that comes with a search for causation with nonexperimental tools.

The Internationalization of Crime and Criminology

While criminology began in Italy and other parts of Europe, it developed and flourished in the United States. While criminology was developing as a social and behavioral science in the United States, in the rest of the world it continued, if it existed at all, as a part of the study of law. In recent years, two changes have occurred, a change more fully developed in the article on 'International/Comparative Criminology' in this Encyclopedia. Criminology has emerged as a social science with an empirical research focus in countries around the world (in England and some Scandinavian countries there is a longer history of criminology, but even in those countries research criminology has expanded in the last 50 years). Crime has become more international. These two developments have resulted in a growing recognition of the importance of an international perspective in criminology. Even in countries without an established field of criminology, there is strong interest in understanding the discipline and how it might be used in their countries (for example, both China and Vietnam have developed in conjunction with the University of Maryland Criminology master's degrees in their countries as a way to stimulate the development of the criminological study of crime and justice (www.oiep.umd.edu)). The study and control of organized crime, drug markets, human trafficking, money laundering, terrorism, and cybercrime inevitably involve an international focus. In short, criminology can no longer be the study of crime only in the United States.

Evidence-Based Policy

In 1984 the United States Congress adopted the Comprehensive Crime Control, which was signed into law by President Regan. One aspect of this law was the requirement that funds distributed by the federal government to the states to address crime had to be used to support programs of proven effectiveness. Only those programs demonstrated to be effective at reducing crime or improving justice could be funded (as with most legislation there were some caveats to this requirement but this intent was very clear (see Title V on the Comprehensive Crime Control Act of 1984)). This requirement was never met primarily because the science required to implement it did not exist. Today, at every level of government the demand is for evidence that existing and new programs 'work.' In the field of criminal and juvenile justice that means the need for more and more research on interventions to control crime and improve justice. The efforts of the Office of Justice Programs to promote this approach are most evident in a Web site that seeks to identify all successful and unsuccessful programs (www.CrimeSolutions.org). The pressure on criminology to conduct rigorous evaluations requires more criminological research and better ways to assemble and assess that research.

The Importance of Partnerships

Criminology is no longer a science that can be done with access to existing data in archives or on shelves. It requires direct access to the objects it studies. This means developing partnerships with law enforcement agencies to gain access to personnel and records, and directly studying and observing offenders. Fortunately, law enforcement agencies have understood the value of criminological research and have encouraged criminologists to partner with them. This is especially true in policing, where, for example, the International Association of Chiefs of Police have produced a guide for chiefs to develop effective research partnerships and have started an annual research award that has as one of its central criteria partnerships with researchers. While prosecutors and correctional officials have not been as welcoming, they too have recognized the necessity for evidence-based policies and practices and thus the need for research enhancements. As for the study of causation, criminology may be approaching the situation in suicide research where the leader of that research community is quoted in the *New York Times* magazine as follows:

> We've never gone out and observed, as an ecologist would or a biologist would go out and observe the thing you're interested in for hours and hours and hours and then understand its basic properties and then work from that, Matthew K. Nock, the director of Harvard University's Laboratory for Clinical and Developmental Research, told me. We've never done it. (June 2013)

The divide between in-depth case and qualitative studies and quantitative research in crime causation is challenged not only by the failure of theory, but the recognition in economics and other social and behavioral sciences that understanding behavior requires deep observation of that behavior and those who engage in it. This may the biggest challenge for criminology in the future.

Abstract

The history of criminology is examined comparatively for four countries or regions: the United States, Latin America, Scandinavia, and the United Kingdom. Each case history considers a common set of analytic dimensions: origin and takeoff (time, discipline, political context); changing shapes (themes, theoretical orientations, data); changing organization (associations, journals, position in universities, government and nonprofit institutes); and the political-economic environment of criminology. Commonalities across national and regional developments and particularities of each region speak to the conditions of criminology. Globalization is at work, partly under US guidance, but academic exports are challenged and adapted to nation-level political, ideological, and institutional contexts.

Criminology, the study of the causes and consequences of crime and societal and governmental responses to crime, is today represented around the globe. Yet, its history and institutionalization vary by country and region. The relative weight of the social science component in this multidisciplinary field has grown over the past century, but its prominence varies as the field cohabits and competes with legally oriented or biologically oriented criminologies. The history and current shape of criminology (from here on referring to social science criminology if not otherwise specified) hinge on economic and political conditions common to all sciences and on the organization of academia within universities, government-sponsored and private institutes, and disciplines already established when criminology emerged.

Four case histories are briefly described below, specifically those of the United States (US), Latin America, Scandinavia, and the United Kingdom (UK). They display commonalities and particularities of criminologies across the globe. Commonalities of academic development across countries and world regions then point at global forces that affect criminology irrespective of its geographic location. Particularities speak to national and regional factors that contribute to local distinctions. Examining commonalities and particularities thus helps us understand the social conditions of criminology and its history. As we examine our four countries/regions, each case history considers a common set of analytic dimensions:

1. Origin and takeoff: time, discipline, political context;
2. Changing shapes: themes, theoretical orientations, data;
3. Changing organization: associations, journals, position in universities, and government and nonprofit institutes. Of interest in its own right, the organization of criminology also affects the substance of criminological work. Relatively autonomous academic organizations free scholars from immediate political and economic concerns and allow for the formation of networks of competition and collaboration (Collins, 1998). Within universities, organizational competition shapes the nature of newly emerging disciplinary units as demonstrated for early twentieth century sociology (Camic, 1995). The organization of departments and journals subsequently affects the content of scholarly work (for criminology see Laub and Sampson, 1991; Savelsberg et al., 2004; Short and Hughes, 2007).
4. Political-economic environment of criminology: While economic surplus is a prerequisite for the differentiation and expansion of science, political context can be restricting and enabling. Historical research on criminology under totalitarianism depicts limitations, while simultaneously showing niches of free exploration within the specialized academic field (Wetzell, 2000 on Nazi Germany). Under liberal democratic regimes, governments affect the substance of criminology through funding of institutions and research or through the stimulation of demand for professional degree programs (Savelsberg and Flood, 2011).

Criminology in the United States

Criminology in the US emerged in the late nineteenth and early twentieth centuries, accompanying social changes that highlighted the need for scientific studies of crime and criminals. Police departments in rapidly growing cities broadened the scope of public responsibility for crime and made that responsibility problematic. Theories concerned with the effects of prison conditions were hotly debated, and innovations proposed; participants in these debates were part of a social movement to construct 'asylums' for criminals and other unfortunates (Rothman, 1971). Concerns for children prompted legal changes, special courts and institutions.

Journalists highlighted the association of crime and social conditions, stimulating government and citizen, as well as scholarly activities. Stirrings of social science concerns with crime in the US are reflected in the 1865 constitution of the American Association for the Promotion of Social Science that referred to goals such as 'Prevention and Repression of Crime,'

and 'Reformation of Criminals' (Lengermann and Neibrugge, 2007: p. 74).

Programmatic scientifically inspired empirical research on the social distribution of juvenile delinquency (Shaw et al., 1929) led to sociological hegemony in criminology, albeit not without challenges from biology (Rafter, 1997), while academic texts marked the autonomy of the field. Criminology was integral to the dramatic growth of social sciences in the US through the 1920s and 1930s (Rice, 1931).

The inherently interdisciplinary nature of criminology created a great deal of theoretical ferment. Robert Merton's (1938) theory of deviant adaptations to structural limitations on goal attainment marked a shift toward an emphasis on social structure. Advances in survey methodology made study of individual delinquents and criminals more efficient. Individual-level research and theory flourished with advances in psychology and social psychology, and economics brought the rational action paradigm to the field.

Criminological theory over the past half century elaborates and adds to insights from these disciplines and from advances in the biological sciences, an early precursor of criminology. Social disorganization theory and Sutherland's (see Cohen et al., 1956) ideas of differential association and differential social organization began a process of formalizing theory in criminology that continues even today. Social learning theory, borrowed from psychology, became a major perspective, as did control and labeling theories, which owed much to their roots in symbolic interaction theory. In recognition of failures to explain variations of regulatory capacities of social relationships and neighborhoods, 'social capital,' an addition to human capital, was in turn added to as 'collective efficacy,' and social disorganization became systemic disorganization.

While macro- and individual-levels of explanation were strengthened by these developments, situational contexts and group processes received less emphasis. However, methodological and theoretical innovations in network analysis and analysis of spatial relationships, together with new technologies for qualitative data analysis, offer promise of more holistic scholarship in criminology (Sampson, 2012).

Formal organization of criminology came about in conjunction with organizations devoted to law enforcement and corrections. The American Society of Criminology evolved from an organization formed initially for the purpose of professionalization of police. The constitution of one of its progenitors defined 'criminology' as 'the study of the causes and prevention of crime, including, but not restricted to,' several law enforcement and crime control goals (Morris, 1975: p. 128).

Implications of research for crime prevention and control have been problems for criminology from its beginnings. Debate also centers on whether criminology is a fundamental discipline or a special interdisciplinary field; and/or an applied vs a theoretical- and research-oriented enterprise. Partisans of the disciplinary view argue that criminology's association with law and its multimethod, theoretical and empirical maturity warrants such recognition. The dependence of criminology on the social science and behavioral science disciplines as well as the influence of extrascholarly influence on the field's subject matter challenge this view. In either case, the lines between criminology and its supporting disciplines increasingly are blurred, as criminologists continue to benefit from and contribute to developments in theories and methods in the social sciences, law, and other special fields, including comparative criminology and Third World human rights and conflict (Hagan and Rymond-Richmond, 2009; Savelsberg and King, 2011).

Criminology in Latin America

Criminology in Latin America was born when ideas of the Italian 'Positivist School' were imported in the 1880s, both in the fields of law and medicine. This importation was stronger in some national contexts such as Argentina, where the Society for Juridical Anthropology was founded in 1888. In the same year, the first Latin American book on criminology was published. Entitled *Los Hombres de Presa* and authored by Luis M. Drago, it was translated into Italian and published with a highly favorable prologue of Cesare Lombroso. The year 1898 witnessed publication of the first scientific journal on criminology in Latin America, entitled *Criminalogia Moderna*. In national contexts like Brazil, Mexico, Cuba, or Argentina, between the end of the nineteenth century and the 1940s, Lombrosian ideas about the 'born criminal' were widely diffused and associated with strong racist connotations.

In reaction to the biological school, challengers emerged in the early twentieth century. They were inspired by the 'French School' that stressed the psychological and sociological dimensions of crime causation (e.g., Debuyst, 1998; Mucchielli, 1994a,b). Most prominent among these scholars was Jose Ingenieros who developed a new classification of criminals. He did not discard the idea of criminals as abnormal, but he explained abnormality entirely in a psychopathological way. Guided by this framework, Latin American universities created first institutional spaces for criminal anthropology and criminology, particularly in Schools of Law and Medicine. Further schools emerged in affiliation with police and prison institutions. For example, in 1907 the Institute of Criminology was created within the National Penitentiary of Buenos Aires, and Ingenieros was appointed its first director. Throughout the first half of the twentieth century, positivist criminology was consistently promoted by dictatorial and authoritarian governments – albeit with important differences across national contexts. This movement's impact on penal laws, culture, and practices was substantial and continues to be recognizable.

This 'golden age' of positivist criminology reached its peak during the 1940s. Following trends in post–World War II Europe, psychiatric and psychological approaches were emphasized. The focus was always on the individual. Yet, this era also witnessed a general decay in the volume and quality of intellectual production. In some countries, this moment was even labeled the 'era of the criminological silence.' Nevertheless, this psychopathologically reoriented positivist criminology generated new degree programs in criminology. Examples are the University of Buenos Aires (Argentina) in 1966 and the University of Nuevo Leon (Mexico) in 1974. These programs, following a medical model, sought to generate professionals for the production of diagnostic and prognostic reports on 'criminals' in judicial and

prison institutions. Yet, these experts barely influenced the construction of crime control policies, a role that continued to be monopolized by criminal law professors.

Also in the 1960s, some Latin American countries began to import sociological criminology, especially from the US. In a further step, the 1970s witnessed a critical criminology taking hold when new ideas from English speaking countries and Italy were translated into Spanish. Law schools were at the epicenter of this movement, particularly in Venezuela, Mexico, and Colombia. The strong connection of this critical criminology with neo-Marxist political and theoretical languages, however, blocked these developments in countries governed by military dictatorships like Brazil and Argentina.

Since the 1980s criminology's opening toward social science and critical theory, in a field previously dominated by positivist criminology, was promoted by the processes of democratization. Critical vocabulary was diffused and institutional spaces multiplied in law schools across Latin America. Nevertheless this intellectual movement did not translate into the creation of new criminology degree programs, while earlier degree programs in the tradition of the positivist school declined and, in some cases, were closed.

At the beginning of the 1990s, building on initiatives of the preceding two decades, numerous researchers from different social sciences (sociology, anthropology, and political science) began to conduct research on crime and crime control, in many cases beyond the label 'criminology' as an institutionalized academic field. These scholars contributed new theoretical perspectives and empirical research. New institutional spaces were opened in schools of social sciences. In general, the relevance of these types of studies increased significantly, beginning in the second half of the 1990s, as issues of crime and crime control moved center stage in political and public debates.

As a consequence, this field of studies assumed, during these last 20 years, a polyvalent and complex structure. Many researchers today produce knowledge in the name of 'criminology,' others work on similar themes but under different disciplinary labels. Again, as empirical research and theoretical discourse expanded, many Latin American universities created new master's degrees in criminology. Law Schools continued to be their prime institutional location. Simultaneously, scientific journals emerged such as *Capítulo Criminológico* (1973) and *Delito y Sociedad* (1992). In short, the newly emerging field of criminology in Latin America is a growing, complex, and polyvalent field. It entails strong contradictions and debates within and faces substantial challenges regarding both knowledge production and policy relevance.

Criminology in Scandinavia

Criminology in Scandinavia, in its intellectual development, conforms to the overall Continental European patterns. Before the establishment of an independent social science criminology, studies of criminal behavior, policy, and law were conducted by scholars with background in psychiatry or law. Yet, after World War II, criminology took off as an independent social science discipline, as distinct from law and psychiatry.

In terms of core ideas and orientations, the Scandinavian development similarly followed the general shifts of twentieth century criminology from the abnormality to the normality paradigm: While earlier scholars considered crime as a manifestation of individual physical or psychological abnormality, criminologists in the postwar years increasingly redefined it as a normal social phenomenon. The aim of understanding crime as a societal phenomenon was adopted early on by progressive lawyers who established so-called associations of criminalists in Denmark (1889), Norway (1892), Sweden (1911), Finland (1934), and Iceland (1949). In the early phase, the gradual 'sociologization' of criminology was spearheaded by socially minded lawyers. In the postwar era, sociologization gathered momentum as sociology proper emerged as the intellectual backbone discipline of criminology. During the 1960s and 1970s, the profession of psychiatry was sidelined from the core of criminology, while criminal law experts have remained central.

Two factors help explain the postwar modernization and empirical sociologization of Scandinavian criminology. First, World War II implied a drastic break and cultural reorientation from the Continental European tradition to the Anglophone world. Most scientific influences came from the US, and Nordic social science rapidly became 'Americanized' (Haney, 2009). Second, since the early 1960s the Nordic governments created a new international organ of cooperation, the Scandinavian Research Council for Criminology (SRCC). Established in 1961, the SRCC has for more than 50 years channeled government funding for social science criminology. In contrast, the weight of university-based criminology varies between the Nordic countries, ranging from Sweden with a very strong university-based criminology to Finland where criminology is nearly nonexistent in universities.

After the late 1960s, the uniformly 'Americanized,' quantitative and positive approach of Nordic criminology ended as the critique of positivism inspired some criminologists to abandon quantitative criminology for the benefit of qualitative and critical approaches. To some extent, national criminology cultures diverged as a result of this antipositivist turn. Over the recent years, the internal cleavages of Scandinavian criminology have widened, a process that culminated in Sweden's secession from the SRCC in 2012.

Irrespective of such rifts, government support remains the most important source of research funding in Scandinavia. It is channeled through the SRCC, government research institutes, government grants toward evaluation studies, and publicly funded universities. An important outlet for publications is now the *Journal of Scandinavian Studies in Criminology and Crime Prevention* (founded in 2000).

In terms of research substance, Nordic criminology is characterized by the paradigm shift from abnormality constructions to the normality perspective. This shift was heavily embedded in the corresponding shift of the preferred data basis of criminology: away from official statistics to survey data on crime. The very first project of the SRCC was the Nordic Draftee Research (NDR) project (1961–64) that also marks the world's first internationally comparative crime survey. The NDR was launched to show empirically that crime was very prevalent and, therefore, statistically normal (for an in-depth history of the normality paradigm shift in US-Scandinavian criminology,

see Kivivuori, 2011). Since then, crime measurement and analysis of real trends, apart from recorded changes, have remained a central concern of Nordic criminology. Victim surveys and self-report surveys have therefore remained favored data sources (Kivivuori and Bernbrug, 2011). The Nordic homicide research tradition has also been strong. It includes groundbreaking internationally comparative work of Finnish criminologist Veli Verkko (1893–1955) who created the world's longest uninterrupted national homicide time series for Sweden and Finland (since 1754). Throughout, Nordic criminology has been concerned with the practical goal of supporting an evidence-informed and nonpunitive penal regime (Kyvsgaard, 2012). Much of the internal cohesion and emotional energy of the Scandinavian criminological research community derives from this motive.

Criminology in the United Kingdom

Criminology in the United Kingdom is an activity with extended antecedents but a relatively short history. As Garland (1988) has shown, the scientific, clinical, and reformist interests of a wide range of practitioners, but initially perhaps especially psychiatrists and social workers, long predated the development of research institutes, or university degree programs, or conferences devoted to the promotion of criminology as a 'subject.'

The generative context for the formation of criminological discourse in Britain thus includes the activities of a range of (mainly quite gradualist) movements for social reform and 'improvement,' often of Protestant religious affiliation; the widespread and intensifying attachment of respectable opinion throughout the later nineteenth and early twentieth centuries to science; and the specific development of a range of institutions and practices aimed at correcting the habits, morals, and lifestyles of the disreputable poor. Emblematic here are such innovations as the Probation of Offenders Act (1907) with its resonant injunction to 'advise, assist, and befriend' the wayward, the 'delinquent,' the inebriated.

In its articulations with the emergent 'penal welfare complex' (Garland, 1985) criminology in Britain thus begins both within and outside 'the state.' These pluralist and interventionist characteristics help to explain why there has never been a predominance either of Beccarian 'Classicism' or of programmatic Positivism in British criminology despite its attachments to science and its proximity to clinical practices. Neither do the textbook oppositions between such 'paradigms' very well describe its eclectic, pragmatic, empiricist, and reformist preferences.

The institutionalization of criminology as a fit subject for study in British universities was profoundly influenced and advanced in the mid-twentieth century by a number of key European émigré intellectuals. Hermann Mannheim established the presence of criminology at the London School of Economics, the single most vital site for social science research in the UK for much of the century, and one with a close set of associations with influential policy communities especially in the Labor and Liberal parties. Mannheim's scholarly work, including the brilliant but now little-consulted *Dilemma of Penal Reform* (1939) and the prescient *Comparative Criminology* (1965) were among the most substantial, and certainly most sociologically informed, of the period. Meanwhile in Cambridge, Leon Radzinowicz set about developing a permanent institutional home for criminology in the unlikely setting of the Law Faculty of Cambridge University. In an autobiography published as late as 1999, Radzinowicz recalls his attraction to English political culture as he encountered it in and after the 1930s. It was, in his eyes, "down to earth, practical, observant, critical" (Radzinowicz, 1999: p. 376). 'England,' he asserts, "made me a realist and a pragmatist" (see further Sparks, 1999: p. 454).

The influence of Radzinowicz on the subsequent development of the subject was distinctive and substantial but nowadays culturally remote. Radzinowicz set out to create an academic field in the image of the virtues that he attributed to British institutions – thoroughness, decency, probity, and a lack of ideological enthusiasm. The formation in 1960 of the Institute of Criminology, with significant and sustained backing from the Home Office, was a watershed in the institutionalization of British criminology. It marks a transition from amateur enthusiasm and 'cottage industry' (Downes, 1988) to academic enterprise. What might seem more unfamiliar to observers beyond the UK (and frequently lamented nowadays by many within it) is the extent to which during the same period the internal research branch of government, the Home Office Research and Planning Unit, also became a major producer of criminological research (Walker, 1988; Newburn, 2011).

Yet even if the 'pragmatic frame of reference' seen as characterizing these institutions (Cohen, 1988: p. 39) was initially dominant it did not take long for it to receive certain significant shocks and challenges. Indeed, criminology rapidly became a focal site for the political and intellectual debates and conflicts that gripped British society in the 1960s. A new generation of social scientists, embarking on academic careers in newly founded universities, engaged with the political and cultural tumult of that decade, and freed from the direct dependency of bodies like the Cambridge Institute on short-term government research funding, brought new objects of inquiry to the fore: deviance, social control, political conflict and state violence, police power, ideology, and the manufacture of news, not to mention the reflexive and intentionally subversive reexamination of the claims and effects of criminology itself.

New theoretical perspectives and concepts took center stage: appreciation, labeling, moral panics, symbolic interactionism, Marxism, and feminism. New institutions were assembled to provide a platform for these perspectives and to build alliances with radical social workers and lawyers, students, prisoners' organizations and campaigns against state violence. Foremost among these were the National Deviancy Conference (1968–79) and the European Group for the Study of Deviance and Social Control (founded in 1973 and still in existence). The radical movement sought to extend criminology's intellectual range and reach, its theoretical ambitions and disciplinary frame of reference as well as adding hugely to its scholarly productivity. For example, in an emblematic contribution *The New Criminology* (Taylor et al., 1973) set out a bold and influential prospectus for a 'fully social' theory of

deviance. The new generation also promoted a more cosmopolitan approach, forming connections with European abolitionists, antipsychiatrists, and a range of other activists and social movements. The small, somewhat insular, rather atheoretical world of 'mainstream' British criminology had been subverted almost as soon as it had been established (see further Loader and Sparks, 2012).

The resulting ironies and fissures are never far to seek in the subsequent development of criminology as a 'discipline.' As the most acute of its radical observer-practitioners notes: "The more successful our attack on the old regime, the more we received PhDs, tenure, publishers' contracts and research funds, appeared on booklists and examination questions, and even became directors of institutes of criminology" (Cohen, 1988: p. 8). Thus, in one of the places in the world where criminology has expanded most rapidly, allegations of its failure, or betrayal or irrelevance are most persistently debated (Loader and Sparks, 2010: Chapter 1). There is a great deal more that might be said – not least that Britain is not now, and has really never been, a single place; and that the criminological cultures of Scotland, Wales, and Northern Ireland merit attention that space here forbids (see, e.g., McAra, 2008).

Criminology in Britain appears to have become one of those academic formations whose 'health' thrives upon what are often negative developments in the institutions it studies – their politicization, the repeated shocks to their legitimacy. It exhibits a permanent duality, as both a critical and a governmental discourse (Garland and Sparks, 2000; Garland, 2011), and to invite takeover bids and denunciations from partisans on either side. Its relationship to government and public policy remains integral, yet unlikely ever to recapture the intimacy, or easy alignment of worldviews, that characterized its birth.

Comparative Notes and Conclusions

Examining the history of criminology in four countries or regions shows common patterns and differences. Common trends during the twentieth century include shifts away from biologically and psychiatrically toward sociologically inspired ways of thinking and conducting research on issues of crime and crime control. They also include an increasing institutionalization of the field, with its own departments, degree programs, journals, and funding sources.

Despite such secular commonalities, differences in the course of these developments and in the current state of criminology are substantial. A social scientifically oriented criminology emerged first and most prominently in the US, reflective of a weak central state in times of rapid societal transformations and massive social problems (Hamilton and Sutton, 1989). Its emergence in Europe coincides only with the end of World War II, and its establishment in Latin America lags even more. The country/region accounts speak to potential explanations. The political context of an academic field with applied leanings obviously matters. A sociologically oriented criminology had chances in Latin America only with the demise of military dictatorships. In Scandinavia, criminology with its centralized government funding takes on a particular character, with specific methodological and thematic foci to reflect concerns of the Scandinavian welfare states. Also in the UK government funding contributed to the establishment of major research initiatives and institutions – even if an academic counterculture soon reacted to this alliance between government and the academy.

We see further that academic fields do not exist in national isolation. The stories about Scandinavia and Latin America are stories of a movement toward globalized criminology, to some degree an example of 'Americanization.' In the UK, given its close historical and linguistic associations with the US, there have also been profound influences, but these have been mediated by markedly different origins, and sharply distinct institutional and political conditions. In short, globalization leaves different traces in different national contexts. Latin American criminology appears to supplement the 'American' type of sociological criminology with a critical criminology that was inspired by translations of Italian and British writings with neo-Marxist leanings. Counter-hegemonic movements in Latin America and the massive tensions and inequalities in its countries appear to inspire this trend within academia. In Scandinavia, American criminology was incorporated in the welfare state concerns of the Nordic countries.

In short, a comparative study of the history of criminologies across countries and regions shows common trends *and* remarkable distinctions. Economic-political contexts, the nature of academic institutions and of the linkage between political-administrative systems and academia contribute to shaping the specific character criminology takes in each country and region. Globalization is at work, partly under US guidance, but academic exports are challenged and adapted to nation-level political, ideological, and institutional contexts.

Critical Criminology

Bruce A Arrigo and Heather Y Bersot, University of North Carolina at Charlotte, Charlotte, NC, USA

Abstract

Central to critical criminology's reformist agenda is the status of the self in society and the structural forces that undermine or thwart human capital. This article historicizes and culturalizes these concerns, mindful of the global political economy. Four specific aspects of the critique include (1) the problem of reification; (2) the risk, captivity, and harm thesis; (3) the criminology of the shadow; and (4) the criminology of the stranger. These issues are discussed in relation to critical criminology's evolving commitment to humanism, citizenship, and social justice.

Introduction: New Developments and Emerging Trends

While traditional criminology seeks to empirically account for the phenomena of crime and deviance, its critical counterpart endeavors to systematically explain the structural problems that plague veritable existence. Thus, at its philosophical core, critical criminology intends to identify and expose extant sociocultural conditions and arrangements that undermine or thwart the potential forces of human capital. This potential extends from the aesthetical (i.e., the realm of consumerism) to the epistemological (i.e., the realm of politics), from the ethical (i.e., the realm of technology) to the ontological (i.e., the realm of culture). This article describes the interdependent and interconnected flows, intensities, and assemblages that situate or define human capital (i.e., possibilities in being/becoming), and from which this unrealized in-and-of-society self makes choice and undertakes action. In addition, the article discusses the present-day challenge of critical criminology to critique and assess the human agency – social structure dynamics in a globalized and informationalized political economy. This is the challenge of 'ultramodern' society.

The Problem of Reification

At the core of critical commentary is the notion of reification. According to Hungarian philosopher Georg Lukacs, reification occurs when "the subject and social relations become object-like, thing-like, abstract, and commodity-like" (Baldwin 2009: p. 381; see also Lukacs, 1971). This "thingification" (Baldwin, 2009: p. 381) process unfolds when humans assign objectlike qualities to their constructions and ideologies, which are then perceived as "facts of nature, [the] result of cosmic laws, or manifestations of divine will" (Berger and Luckmann, 1966: p. 33). In other words, reification fosters a state in which the distinction between the social person and objects outside the self are, in essence, no longer discernible. This section delineates the three historical and cultural shifts that have abstracted the social person's humanness. These abstractions constitute inversions in being and becoming; harms to human capital.

Marx and Reification

German philosopher Karl Marx's economic theory concerning class consciousness and the "abstraction of the worker" (Arrigo, 2006: p. 45) principally defined the first shift. In the political economy of capitalism, he argued that an economic formula of this kind required the perpetual circulation of money (i.e., capital). However, as Marx reasoned, the accumulation of wealth generated by labor mostly served the interests of bourgeoisie or capitalist interests (i.e., acquiring through production) rather than proletariat or laborer needs (i.e., being self and other sufficient through production). The dialectical flows and intensities that followed from such conflicting worldviews fueled collectivist struggle to overcome the harm-sustaining acquisitive conditions of production (see e.g., Lynch and Michalowski, 2006). Indeed, as Marx (1990) asserted, in the capitalist mode of production, the intrinsic use-value of one's labor is assigned a fixed, although artificial, exchange (i.e., monetary) value capable of being purchased in the marketplace. In this way, the worker and the product of one's labor are, in essence, rendered a commodity. Marx (1990) described this concept as follows:

> Not an atom of matter enters into the objectivity of commodities as values; in this it is the direct opposite of the coarsely sensuous objectivity of commodities as physical objects. We may twist and turn a single commodity as we wish; it remains impossible to grasp it as a thing possessing value. However, let us remember that commodities possess an objective character as values only in so far as they are all expressions of an identical social substance, human labour, that their objective character as values is therefore purely social. From this it follows self-evidently that it can only appear in the social relation between commodity and commodity. (pp. 138–139)

Made abstract, Marx (1995) posited that the worker "sinks to the level of a commodity and becomes indeed the most wretched of commodities" (p. 70). Accordingly, qualities inherent to the worker/social person's humanness, such as love, virtue, and conscience, "enter into commerce" (Marx, 1995: p. 36), altering the nature of the human relationship

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45053-1

from one of authentic interaction to one of mere transaction. As Fromm (1994) noted,

> It becomes [the individual's] fate to contribute to the growth of the economic system, to amass capital, not for the purpose of [one's] own happiness or salvation, but as an end in itself. [The individual thus becomes] a cog in the vast economic machine – an important one if he [or she] has capital, an insignificant one if he [or she] has none – but always a cog to serve a purpose outside of the [self]. (p. 110)

In the political economy of capitalism, then, the notion of *having* rather than *being/becoming* (or acquiring rather than creating) dangerously and perniciously prevails, thereby disrupting intrinsic social bonds and alienating possibility/potential for collectivist good. Critical commentators have contended that this state of captivity through consumption (see e.g., Chambliss and Seidman, 1971; Quinney, 1974) – which Marx (1990) described as commodity fetishism – extends from "the kept (workers) to their keepers (factory owners), from their managers (institutional decision-brokers) to their watchers (state government bureaucrats)" (Arrigo and Milovanovic, 2009; see also e.g., Rusche and Kirchheimer, 1968; Pashukanis, 2002).

The Situationists and Reification

Drawing upon Marx's commodity concept, a group of predominately European activists known as the Situationists responded to what they viewed as the second major shift or transition concerning the problem of reification. As information technology advanced under late capitalism, these social and cultural theorists sought to challenge the ways in which the mass media manufactured imitative realities (e.g., by way of government propaganda) and stylized consumerism (e.g., by way of crass commercialism). The conspicuous presence of these political economic conditions sustained the decline of being/becoming into having, and transformed the ontological status of having into vacuous appearing (Debord, 1983). In response to this state of affairs, the Situationists mobilized, organized, and promoted the notion of constructing situations, or environments, to counter what they took to be the increasing degradation or abstraction of the social person (Debord, 1983; Lukacs, 1971).

Guy Debord (1983), a leader in the Situationist movement, developed the concept of the spectacle to explain the way in which late capitalism engendered an insidious form of hegemonic repression and alienation. In his compilation of theses, entitled *The Society of the Spectacle*, Debord (1983) contended that "[i]n societies dominated by modern conditions of production, life is presented as an immense accumulation of spectacles. Everything that was directly lived has receded into a representation" (thesis 1). Thus, following Debord, the social person's humanness is further reified by way of images that depict only fabricated and fictionalized constructions (i.e., spectacles) of meaningful life. When these contrived representations are culturalized (i.e., circulated for mass consumer consumption), they become the image-crafted commodities of a consumer society driven insatiably by illusions. This, then, is the "moment when the commodity [as appearance] attains the total consumption of social life" (Debord, 1983: p. 42). Under these conditions, matter and materiality are supplanted by replicas and façades. Indeed, the self in society as human capital is further abstracted through the iterative reproduction of liquid identities and simulated realities that caricaturize, sensationalize, and derealize visceral (i.e., embodied) existence (Bauman, 2000).

The Hyper-Realists and Reification

The third historical and cultural shift was marked by the hyperrealists. Following the Situationists' notion of the spectacle (appearing over being/becoming), these thinkers chiefly concerned themselves with discerning whether contrived representations (i.e., images of reality) were more real than the reality on which they (these representations) were based. In response, the hyperrealists proposed a novel social theory that "elevated the commodification of illusion to a novel and disturbing (alienating) level of abstraction" (Arrigo and Bersot, 2013).

One of the preeminent hyperrealists, French philosopher Jean Baudrillard, asserted that postmodern societies are not organized around production and consumption (i.e., having) as Marx maintained. Rather, Baudrillard (1968, 1972) argued that social life in the new reification era was mediated by simulation. This was an era that no longer made sustainable the replication of appearance over being/becoming as a cultural artifact. In its place, simulation (i.e., the replication and proliferation of image) made coded meanings (systems of communication) the essential artifacts of culture. Indeed, in a digitized information age, reality (or the appearance of it) becomes irrelevant (Baudrillard, 1983a, 1983b). The ascendancy of the code's status (and with it the ungrounding of existence and its manifold illusions), led Baudrillard (1993) to conclude that social life as we knew it had ended. As he proclaimed,

> The end of labor. The end of production. The end of political economy. The end of the signifier/signified dialectic which facilitates the accumulation of knowledge and of meaning, the linear syntagma of cumulative discourse. And at the same time, the end simultaneously of the exchange value/use value dialectic which is the only thing that makes accumulation and social production possible. The end of linear dimensions of discourse. The end of the linear dimension of the commodity. The end of the classical era of the sign. The end of the era of production. (p. 8)

As such, Baudrillard (1983a) suggested that within postmodern culture, significance, or value, could only be expressed through sign-exchange-value. In this new epoch, commodity forms "circulate in the marketplace of signs, anchored, although temporarily, in the dominant sign meanings assigned to them in a particular political economy" (Arrigo, 2006: p. 48). Consequently, as several critical criminologists and cultural critics have warned, this consumption, hypervigilantly reproduced and panoptically (Foucault, 1977) and synoptically (Mathiesen, 1997) disseminated, signifies nothing real other than the fictionalized fear that it feeds for a simulated society of commodified captives (Arrigo and Bersot, 2013; Delanda,

2006; Dyer-Witheford, 1999). Thus, in the hyperreal society, "there is no longer a real to be recovered behind the illusion [and, thus,] there is no illusion either" (Best, 1989: p. 37). Given these conditions of reification, human capital's potential is obliterated.

The Risk–Captivity–Harm Thesis

Recent developments in critical criminology point to reification and how this problem is related to a larger cultural crisis (Arrigo, 2010, 2011, 2012). Specifically, commentators assert that what is reified is (1) risk or excessive investments in fearmongering that manages difference or human capital as sameness through reductive/repress mechanisms and techniques; (2) captivity or the confinement of individual and collectivist consciousness that follows from nurturing or sustaining such mundane risk management practices; and (3) harm or the recursive restrictions that limit possibilities in being and/or deny potentials in becoming for and about one and all when difference is reduced to and repressed by serialized codes. These reifications constitute the cultural crisis of the present ultramodern era. In this section, risk, captivity, and harm and the unreflective maintenance of the thesis are discussed.

Contemporary critical thinkers contend that what is cultivated within a culture of consumption is risk-minded systemic pathology (Fromm, 1994) that silences dissent and suppresses difference. Indeed, current political economic conditions worldwide are indicative of what Beck (1992; see also 2009) termed the 'risk society.' The resulting social dis-ease fosters negative freedom (freedom from rather than freedom to) (Fromm, 1994), and is perhaps made most disturbingly apparent in the industry of crime. The rapid development of penal institutions and their exploitation of inmate labor, the trade in diversion courts, and the vast expansion of surveillance policing are deemed "healthy, natural and inevitable threat-avoidance progress" (Arrigo and Bersot, 2013). Although such measures promote economic growth consistent with capitalism in the ultramodern era, some critical scholars posit that the industry of crime normalizes violence by way of engendering a palpable sense of abject fear among the citizenry (Simon, 2009). This is fear with transnational harm-intensifying human consequences (Bauman, 1998).

To illustrate, consider the dramatic surge in surveillance technology. These monitoring mechanisms and techniques – defined by some as emblematic of the "prison-release-reincarnation abstract machine" (Arrigo, 2012: p. 441; see also Arrigo and Milovanovic, 2009; Deleuze and Guattari, 1987) – include radio frequency identification (e.g., to supervise registered sex offenders within the community) and global positioning systems (e.g., to locate diverted juveniles) (Bowling et al., 2009; Grabosky, 1998). While the expressed aim of these measures may be to protect the public, "risk" is "connected to future offenders, not victims" (Schinkel, 2011: p. 370). Thus, they (these mechanisms and techniques of surveillance) are deployed to manage potential crime rather than respond to actual crime.

Derivative in its consumerism and digital in its politics, this machine serializes (i.e., makes abstract, deontologizes) the experiences of crime and justice, law and order, violence and victimization by semiotically reducing and repressing objects, events, and individuals to nothing more than informational (i.e., coded) utility. Biopolitical tattooing, social sorting, and prepression are all measures that have been created and/or reintroduced as means to manage risk – eliminating difference and imposing sameness within society. Biopolitical tattooing involves inspecting and monitoring the very body of an individual by way of subcutaneous tattoos and finger and retina prints (Agamben, 2004). Social sorting refers to the way in which (inter)national surveillance measures, particularly in the post-9/11 world, are "coded to categorize personal data such that people [digitally identified as potential threats]…may be treated differently" (Lyon, 2007: p. 162; see also 2003 and 2006). Prepression is a "combination of prevention and repression [that] entails the archiving of risky individuals (e.g., children who display problematic behavior) and their selection for 'early intervention'" (Schinkel, 2011: p. 365).

What emerges from these hyperreal meaning-making/generating risk practices is captivity. The harm of this captivity extends to and from the kept (i.e., those incarcerated, civilly committed, and otherwise subjected to inspection and monitoring within the community), their keepers (e.g., correctional staff and police officers), their regulators (e.g., policy makers, judges, and correctional administrators), and their watchers (i.e., the public) (Arrigo et al., 2011). Indeed, the quality of this captivity is one that confines individual and collectivist consciousness. Drawing upon Foucault's (1977) work on the disciplinary society, French philosopher Gilles Deleuze (1992) proposed the notion of the control society. He described this intellectual transition as follows:

> In the societies of control, on the other hand, what is important is no longer either a signature or a number, but a code: the code is a password, while on the other hand disciplinary societies are regulated by watchwords (as much as from the point of view of integration as from that of resistance). The numerical language of control is made of codes that mark access to information, or reject it. We no longer find ourselves dealing with the mass/individual pair. Individuals have become "dividuals," and masses, samples, data, markets, or "banks." […] The disciplinary [subject] was a discontinuous producer of energy, but the [subject or person] of control is undulatory, in orbit, in a continuous network. (Deleuze, 1992: p. 6)

Thus, the society of control reduces and represses human subjectivity by way of propagating fear about would-be offending/offenders through the numeric serialization of human capital. This fear induces a sense of complacency toward the ubiquity of surveillance technology and its disturbing risk-management flows, intensities, and assemblages (i.e., tagging, tracking, neutralizing, and eliminating would-be offenders). Although such technologies seemingly ameliorate collective anxieties about the deviant (e.g., juveniles whose violent tendencies belie their youthful innocence), the diseased (e.g., sex offenders who are incapable of being cured from their perverse proclivities), and the *potential* dangerousness of both constituencies, the 'informationalizing' that follows from the control society is normalized harm. The violence of this

informationalizing implicates – and captivates – one and all. By vanquishing difference (i.e., derealizing it through its serialized coding), the resulting harm territorializes freedom, citizenship, and social justice and their embodied human capital significations. Thus, greater possibilities in being and increased prospects for becoming are constrained or foreclosed.

The Criminology of the Shadow

Amidst the ultramodern crisis are troubling conditions of control that interdependently sustain the criminology of the shadow (Arrigo, 2008, 2012; Arrigo and Williams, 2009). Finding its origins in Plato's (2008) appearance/reality thesis, the shadow represents a critique of the in-and-of-society self (Arrigo, 2011, 2012). The criminological status to which this crisis refers is the social person's reification captured within and subjected to four forces of destabilizing influence. These interdependent, mutually supporting, and coproductive forces or control conditions consist of symbolic (aesthetic), linguistic (epistemological), material (ethical), and cultural (ontological) flows, intensities, and assemblages. The harms sustained by these influencing conditions extend to and from the kept (i.e., those confined), their keepers (i.e., those who confine), their managers (i.e., those who administrate confinement), and their watchers (i.e., those who observe confinement) (Arrigo et al., 2011; Arrigo and Milovanovic, 2009). The section below delineates the conditions of control and the violence that is normalized (i.e., totalizing madness that is made healthy and normative) by way of these captivating forces.

The Symbolic Realm and the Ultramodern Shadow

The symbolic realm consists of sign-exchange-value. Sign-exchange-value refers to the images, or symbolic constructions, that are mobilized and activated in the unconscious. Although always fragmented or incomplete, these images (i.e., pictures in our minds) mediate prevailing articulations (i.e., master discourses) (Lacan, 1977, 1981) for and about the same. This includes mental constructions for and about offenders and victims; institutional and community-based treatment for these citizen groups or from these governmental entities; and agency, responsibility, and choice for all stakeholders. Thus, for example, what images are conjured in one's mind (dominate individual and collectivist consciousness) when it comes to juvenile delinquents, mentally ill individuals, and sexually violent predators? If the imagined construction tells the story of delinquency, disease, and dangerousness (i.e., the social person is defined only as the 'lack' in discourse), then much is missing from such psychic configurations. This is the self in society as mere shadow in mental representation. Conversely, image-crafting the social person as delinquent, diseased, and dangerous human potential involves the production and circulation of speech that, although incomplete, affirms this yet-to-be-fully envisioned subjectivity (Lacan, 1977, 1981). What is hidden through the ascendancy of the master discourse is a "struggle whose aesthetic intensity (about human agency) and force (concerning structural meaning) dangerously (i.e., panoptically and synoptically) linger as desperation and fear respectively" (Arrigo and Bersot, 2013). Thus, the struggle in being/becoming entails recognizing and transforming circumscribed, although dominant, symbolic constructions that are consumed by way of sign-exchange-value. These images incompletely symbolize human capital's potential.

The Linguistic Realm and the Ultramodern Shadow

The linguistic realm consists of sign-exchange-value emanating from the unconscious that is translated into speech or the written word. Because the symbolic realm consists of inadequate and partial representations, the text that emerges from this imaging is likewise unfinished and insufficient. Indeed, the unconscious narrative that flows from these symbolizations "communicates less than (produces less about) who we are or could become" (Arrigo and Bersot, 2013). What is produced through this semiotic process is the mass-marketing of fictions about human capital manifested by way of the 'presencing' (privileging) of selected knowledge. "As narrative, [this preferred text] enters the marketplace of sign-exchange-value and recounts the struggle of the [social person] in its own governing voice. This voice tells of desperation and fear through the epistemology of logocentrism and the metaphysics of presence" (Arrigo and Bersot, 2013; see also Derrida, 1973, 1977, 1978). The concept of logocentrism suggests that what is most readily accessible to consciousness is that which is fundamentally defined as good and virtuous. Thus, the values attached to these discernible and manifest notions are rendered true and absolute. However, under these textual conditions, the narrative that is produced and reproduced is one that tends toward finalization (Bakhtin, 1982). This is the self in society as mere shadow in words. When these fragmented renditions of truth, progress, science, and human potential are written and rewritten, the possibilities for articulating alternative narratives are forestalled or, worst, excluded (Deleuze, 1983). As such, the texts for and about the social person's emergent possibilities in being and becoming await emancipation and inscription.

The Material Realm and the Ultramodern Shadow

The ethos of the material realm entails inhabiting the favored texts of human potential – and all their incompletenesses and partialities – as lived history, as embodied truth. These truths materialize as systems of thought and bodies of knowledge (e.g., in psychiatry, law, penology, social work, education, and the like) that domesticate and discipline the social person's humanness. This domestication and disciplining is power materialized corporeally. Biopower relies on techniques and mechanisms that depathologize (Foucault, 1965, 1977) and territorialize (Deleuze, 1983) being/becoming. Under these material conditions, "difference is vanquished…, identity is homogenized, and community is sanitized" (Arrigo et al., 2011: p. 165; Arrigo, 2010). This is the self in society as mere shadow in its embodiments.

Indeed, as Fromm (1994) cautioned when diagnosing the status of the captured social person,

> The individual ceases to be [and] adopts entirely the kind of personality offered to him [or her] by the cultural patterns; and [the individual] therefore becomes exactly as all others are and as they expect [the individual] to be. The discrepancy between "I" and the world disappears and with it the conscious fear of aloneness and powerlessness…[t]he person who gives up his [or her] individual self becomes an automaton, identical with millions of other automatons…[and] need not feel alone or anxious anymore. But the price [the individual] pays, however, is high; it is the loss of the self. (p. 184)

Under these material conditions, then, subjects are rendered docile bodies amenable to the will of the state (Foucault, 1977: p. 210; see also Arrigo et al., 2005). What is normalized by way of this domestication and disciplining is violence corporealized (i.e., the self and other habitations of captivity's shadow).

The Cultural Realm and the Ultramodern Shadow

The cultural realm encompasses the sphere of replication and dissemination – in image, text, and bodies of knowledge. Given the partial portraits, incomplete texts, and disembodied systems of knowledge that govern human capital, caricatured representations of each prevail in the ultramodern age. This is the era of digital interconnectivity and hyperreal information-only interdependency. This is the condition of carnival consumption (Carrabine, 2008), fast capitalism (Agger, 1989), and liquid identities (Bauman, 2000) in which the virtual rather than the visceral, the sensational over the sensual is ontologized (Arrigo et al., 2011). What is absent in this culturalizing of the social person is human potential as being/becoming – as yet-to-be imagined, spoken, scripted, and inhabited productivity. What remains, then, is the self in and of society as mere shadow in its cultural artifacts and political economic abstractions. This is human potential restricted in images, texts, and systems of thought that are simulated derivatively serially, and ubiquitously.

When these collective conditions of control are maintained and nurtured as healthy and normative pathways to progress, the all-encompassing consumption of the criminological shadow is made more immanent. Currently, the intersection of image, language, embodied subjectivity, and their cultural reproductions reify fragments and fictions of human capital. Sustaining these conditions is madness. Succumbing uncritically to these limits on and denials of being/becoming is totalizing madness (Arrigo et al., 2011). Recognizing and overcoming the human capital harm of this captivity is a journey in the making; it is a revolution for people yet to come (Deleuze and Guattari, 1987).

The Criminology of the Stranger

As described previously, the coproductive, mutually supporting, and interdependent flows, intensities, and assemblages of ultramodernity exert symbolic, linguistic, and material force on the self in society. The current cultural artifacts and political economic abstractions that emerge from these exertions sustain harm-intensifying/generating conditions of control. These influencing conditions reduce possibilities in being and repress prospects for becoming. Consequently, the quality of citizenship and the character of social justice are less than what they could be for, by and about one and all. The ultramodern journey that awaits development is the exploration, cultivation, and occupation of novel and derelict flows, intensities, and assemblages. This is habitus – the horizon of perception, thought, and action (Bourdieu, 1977) – as experimental, creative, and dynamic. When habitus is envisioned, spoken of, and practiced as such, it provides the positional, relational, and provisional grounding from within which human capital's potential as productive change (as freedom) can emerge. This undertaking, then, is a mutating and unfamiliar revolution for people yet to be (Arrigo and Milovanovic, 2009).

The counterpoint to the criminological shadow is the criminological stranger (Arrigo and Milovanovic, 2009). The stranger seeks to liberate the desiring subject (i.e., the social person in captivity) from harm-intensifying/generating abstractions. The stranger's evolving flows, intensities, and assemblages offer a way out of the ultramodern crisis of reified madness that the criminological shadow fetishizes and normalizes. This 'way out' includes departures in theory (the consumerism of critical mindfulness), method (the politics of difference), and praxis (the corporealizations of excellence). These exits are briefly discussed, especially in relation to their capacity to reconceive critical criminology in ways that hold the nearest promise to unleash and harness dormant human capital.

As a departure in theory, the journey entails embracing a cosmopolitan imagination (Delanty, 2009). This is image, language, and embodied subjectivity reconceived within the jurisprudence, the landscape, of the mind. This cosmopolitanism symbolizes (image crafts) 'offenders,' 'victims,' 'crime,' 'punishment,' 'recovery,' 'human agency,' 'social structure,' etc. differently (e.g., doing drug treatment and recovery another way; doing victim offender mediation another way; doing community policing another way). These are mental constructions that are resistant to closure, to the finalization of being, and to the criminological shadow's reification. To access this "reservoir of desire" (Arrigo and Bersot, 2013), the master discourses that govern consciousness must be excavated and deterritorialized (Deleuze and Guattari, 1987) for their harm-producing tendencies. These tendencies include the normalization of violence that renders the social person's difference (one's human potential) as lacking in consciousness. Deterritorialization is genealogical in its operation. It involves mining and uprooting the unconscious, its topography, and the Oedipal and capital logics that the psychic apparatus both privileges and endorses (Arrigo and Milovanovic, 2009). Critical criminology's challenge by way of cosmopolitanism, then, is to disassemble the hyperreal shadows of difference that criminology reproduces, and to reterritorialize (i.e., reassemble, reconstruct) criminology's serialized terrain in ways that harness will to power (Nietzsche, 1968). Power refers to desire (latent being/becoming) mobilized in the service of unleashing human capital's potential. The consumerism of critical mindfulness awaits additional theoretical development and amplification.

As a methodological exit, the criminology of the stranger entails movement outside of consciousness to the texts that narrate or tell the story of law and order, freedom and punishment, offenders and victims, treatment and recovery, self and society, etc. This movement – situated within the flows of deterritorialization and reterritorialization – entails journeying as a being toward difference, tending ever more so toward dynamic and transformative (rather than unchanged and uniformed) descriptions of human capital. These are the narratives of how the social person (e.g., as a recovering drug abuser, exincarcerate, and mental health consumer) makes overcoming possible because of, rather than despite, one's status as addict, convict, or patient. The challenge of critical criminology is to speak of, write about, and circulate these creative, provocative, and experimental stories of overcoming through difference. These narratives constitute a 'strange' humanness whose inscriptions tell of human capital's uncharted possibilities in being and unexplored prospects for becoming. This difference implicates one and all in an era that reifies hyperreality; derealizes risk, captivity, and harm; and serially codes the criminological shadow. The 'politics' of difference as method awaits further analytical refinement.

As a venture in praxis, the criminological stranger seeks to produce different lived histories about crime making and peace building, citizenship and community, and agency and structure. This is embodied subjectivity steeped in replacement systems of thought and alternative bodies of knowledge that manufacture mutating habits of excellence (Aristotle, 1976). This excellence or flourishing is human capital corporealized differently, as being/becoming virtuous. What is corporealized is human capital's dynamic potential lived ever more courageously, compassionately, responsibly, generously, etc. when studying crime; making peace; doing citizenship; residing within neighborhoods; and inhabiting class, race, and gender categories or their intersectional configurations. These embodiments transform the social person into a subject in-process (i.e., embodying one's difference another way). Critical criminology's challenge, then, is to occupy (territorialize) absent bodies of knowledge and heterodox systems of thought through mutating habits of excellence. This is the evolving journey of becoming ethically revolutionary. The proposed revolution dignifies, honors, and affirms all those within the society of captives and extols the potential forces that emancipate human capital. The corporealizations of excellence as praxis await supplementary and systematic delineation.

Abstract

Critical legal studies is a label for movements of leftist legal academics in the USA, Britain, and France which reached their height of influence in the 1980s and 1990s. Critics target their critiques to the dominant modes of legal reasoning, scholarship, and teaching in their legal cultures. These modes usually pretend to be neutral and apolitical, but critics see them as expressions of conflicting political ideologies. Critics do not assume law is merely a superstructural reflection of a material base of determining economic relations, or as simply an instrument of ruling-class power, but treat the content and forms of law and legal reasoning as relatively autonomous active force fields in the structuration and interpretation of the economy and social world. Ideologies hidden in law often serve to produce, reproduce, and justify inequalities and illegitimate hierarchies; but they also express utopian aspirations and point to plausible alternative social arrangements. The critics' aims have been to bring into view the latent ideologies and contradictory structures of the legal order, and to capture and reorient enclaves of legal scholarship, teaching, and practice, and to use them to reimagine and incrementally put into practice alternative legal ideas and policies.

'Critical legal studies' (CLS) is an umbrella term for a variety of movements of legal intellectuals, most of them in law faculties in the USA, Britain, and France. The movements originated in the late 1970s and achieved their peak of influence in the 1980s and 1990s. Their adherents are generally on the political left, critical of existing distributions of wealth, power and status rewards and of patterns of domination and subordination by class, race, gender, and other 'illegitimate hierarchies.' Unlike classical Marxists, they do not treat law as a merely 'superstructural' reflection of a material' base' of determining economic relations, or as simply an instrument of ruling-class power; they take the content and forms of law and legal reasoning seriously, as relatively autonomous active force fields in the construction and interpretation of the social world. Critics (or 'crits') target their critiques to the dominant modes of legal reasoning, scholarship, and teaching in their legal cultures, which usually pretend to be neutral and apolitical, but which the critics see as expressions of conflicting political ideologies. The ideologies hidden in law often serve to produce, reproduce, and justify inequalities and illegitimate hierarchies, but they also express utopian aspirations and point to plausible alternative social arrangements. The critics' general aims have been to bring into view the hidden ideological biases and effects of the existing legal order, to capture and re-orient enclaves of legal scholarship, teaching, and practice, and to use them to re-imagine and to implement alternative legal ideas and policies.

Within these broad commonalities of outlook and concern, the CLS movements have tended to fragment into many different schools, informed by diverse intellectual antecedents and committed to divergent views of the role of law in social life and of the political ambitions of intellectual critique and reform.

The US movements receive most attention here, since they attracted the most members, produced the largest literature, and penetrated the furthest into centers of legal education; also, their types of scholarship and internal quarrels parallel those of CLS movements elsewhere. CLS-USA came into being in 1977 at a conference of law teachers rebelling against their own legal education and its seeming irrelevance to the contemporary ferment of social movements (anti-Vietnam War, civil rights, feminist, environmental, etc.). By the 1980s critical teachers made up a significant fraction (four or more faculty) at Buffalo, Harvard, Miami, Northeastern, Stanford, UCLA, and Wisconsin law schools and a token presence at many more, eventually producing students who went into law teaching themselves, a substantial bibliography (Kennedy and Klare, 1984; Bauman, 1996), and a series of national conferences.

Antecedents of CLS

To critique the orthodoxies of their legal culture, American critics in the first phase of their movement found resources in various European theories, especially Western neo-Marxist theories of law as 'ideology' and an instrument of 'hegemony' (Gramsci, 1971), humanist social histories of subordinated groups (Hay, 1975; Thompson, 1975), structuralism, and phenomenology. But their main resource turned out to be their domestic forerunners, the American legal realists of the 1920s and 1930s who critiqued the classical-formalist legal orthodoxy of their own day (*see* Legal Realism; Legal Formalism). That orthodoxy had claimed that the operating rules of the legal system could be derived from a few basic principles induced from a scientific arrangement of precedents, such as the protection of property, the basing of liability to others on 'fault,' and the enforcement of the 'free will' of parties to contracts. This system added up to a natural and neutral mode of ordering private life, and legislative interferences with this system of rules would be struck down as unconstitutional unless they met strict tests of validity.

The realists' critique, in brief, was that (1) the principles were too vague, and the precedents too flexible, to determine outcomes, and in actual operation produced results varying over time and with contexts; (2) the actual determinants of results were latent and unarticulated policies, ideologies, and social vision; and (3) the 'private' law rules of property-tort-contract that undergirded the natural-seeming private sphere of

free choice in free markets, protected against interference by constitutional law, were no less artificial, no less exercises of state policy, and no less coercive, than the 'public' rules of legislation and administration. A property right, for example, delegated to its owner the ultimate power to use state force (self-help, private guards, the police or the army) to exclude others (such as union members or black people) he did not want to hire or deal with, and to condition access to his property (tools, land, wages, the assets of a marriage) on those others' submitting to his orders. The coercive state was always involved in the market and business firms and family life; the issues for legal policy were thus not *whether* the state should be involved, but *how*, and *to what ends* – issues that courts, as well as legislatures and administrative agencies, could not avoid and had to resolve.

By the 1950s and 1960s, however, the leading currents of American legal thought had settled into a new orthodoxy, one that absorbed elements of the realist critique but blunted its more radical implications (*see* Legal Scholarship). Some postwar schools held that law (including law made by judges), although not autonomous from clashing social interests, had neutral craft techniques for balancing those interests; others that law properly interpreted served social purposes on which there was presumed to be a general consensus; and others that courts differed from legislatures in that judge-made law promoted general 'principles' rather than specific 'policies.' In the late 1960s, emerging schools of law-and-economics sought to rationalize legal doctrine, especially the private law of property, tort, and contract, as serving the aims of efficiency or wealth maximization. (For an overview see Duxbury, 1995; *see* Law and Economics.)

Early CLS

CLS began as a set of critiques of these postwar modes of legal reasoning. Unlike other movements that carried on the legal-realist critiques, such as the law-and-society movement (which investigated empirically the social influences that helped to form, and the actual social effects of, legal rules), the critics deployed an internal critique: attacking the prevalent modes of doctrinal and policy argument practiced by law teachers, judges, and other officials on their own terms, aiming to develop counterarguments to teach to law students and practicing lawyers.

Following neo-Marxist writers and the critical social theorists of the Frankfurt School, the critics pictured legal doctrines and arguments ('legal discourses') as ideology, a partial vision of the world that presents itself as a universal vision. These discourses function so as to portray existing constellations of rights, powers, privileges, and immunities recognized by the legal system as if they were natural and inevitable ('false necessity'), and as close to being good as they could be ('false legitimation'). By such means the law 'reifies' and thus helps to freeze in place scripted social roles such as manager and worker, landlord and tenant, husband and wife, consumer debtor and bank creditor, property owner and picketing laborer, that blind the ordinary people who play those roles to alternative possibilities for action and organization (see, e.g., Gabel, 1980).

Like the legal realists, the critics' method was to unearth and make transparent the latent subtexts of legal doctrines and policies, the hidden framing conceptions, empirical assumptions, and social visions on which conventional legal reasoning, and the scripted social roles it gave people to play, relied. But the aim was not simply to unmask; it was to develop alternative doctrinal and policy arguments in particular fields of law, and by so doing to open a path for a revisionary politics based on different views of social reality and human potential.

In its first decade, CLS developed a distinctive model of such critiques, which, taught to and adapted by adherents and disciples, was replicated in about 100 articles covering a wide variety of legal fields. The model critique identified some deep-level tensions, polarities, or contradictions underlying a field of legal policy or argument. In a pioneering article, Kennedy argued that contract law doctrines tended to cluster around opposing conceptions of human nature, social obligation, and the functions of law: one favoring formal rules and 'individualist' views of economic transactions and social duty, the other favoring informal standards and 'altruist' ethics of sharing and cooperation (Kennedy, 1976). The law in force at any given time oscillates between the opposing poles as it moves from one subject to another, but tends to privilege one pole and suppress the other, reserving it for exceptional or marginal situations.

Doctrines from the suppressed pole, however, are always available as a 'dangerous supplement' which at any moment may, and sometimes do take over the privileged position (Kelman, 1987). One pioneer (Unger, 1975) generalized the critique across legal fields to 'liberalism' as a whole; but most practiced it as a form of local critique, whose content varied with the field of law that was being criticized. The model also spawned its own genre of structuralist legal history, showing how legal fields come to be structured around contradictory organizing principles and social visions. For example, doctrines reflect people's need for other people and fear of them; the desire for a state powerful enough to protect rights that will not also trample them, and for contract and property law that will carry out parties' intentions and underwrite their freedom of action but also protect their (and others') security. The legal system tries to 'mediate' the contradictory doctrines by confining each to a limited field of operation, yet such systems become unstable as the mediating devices become incoherent and exceptions spill over limits to swamp the rules (see, e.g., Alexander, 1987; Kennedy, 1979; Mensch, 1982).

This strand of CLS was often misunderstood. Critics argued that the structuring of legal fields around such 'contradictions' meant that law was 'indeterminate' because it could (and historically often did) enable judges, advocates, or reformers to make valid arguments (according to internal criteria of the legal system) for opposed positions. Doctrinal or policy arguments could always be 'flipped' by appealing to principles at the opposite pole. This did not mean that law was a facade, sham, or arbitrary meaningless jumble, or that doctrine was just a mask for raw political choice; rather, its indeterminacy was patterned and systemic, an effect of law's (or liberalism's) contradictory structures. Nor did it mean that law was unpredictable, because arguments drawn from one pole or another tended to be stable in the medium term. Nor, finally, was it an indictment of a legal system to say that it was 'indeterminate.' It

was merely a fact, one papered over by mediating devices leading to the appearance of natural, necessary, and almost-as-good-as-it-could-be law.

Later CLS

CLS also extended the method beyond private law doctrine to the powerful emerging new forms of policy analysis, legal economics, attacking certain core premises of the new science including the Coase theorem, cost-benefit analysis of legal entitlements, public choice theory, and submission to the will of others as rational consent (see, e.g., Kennedy and Michelman, 1980). Others extended it to institutions: Simon identified opposed models of welfare administration, mechanical rule-application by low-skilled workers and the professional informal discretion of caseworkers. He showed how the welfare system had evolved from discretion to rules with damaging results for clients and argued for restoration of discretion (Simon, 1983).

Critics also revived and extended the legal realists' critique of the distinction between 'public' (coercive regulatory) and 'private' (freely willed contractual consensual market) relations. Following the realist R. L. Hale (see Fried, 1998 for an intellectual biography), they argued that all 'free choice' is made by actors with property and power endowments and under baseline conditions structured by the legal system, even choice in the most intimate spheres of life such as marriage relations. Their aim was to supplement Foucault's (1977) account of the pervasive regulation of social interactions through 'disciplines' with an account of the pervasive structuration of transactions and interactions in business and personal life through law.

Much critical effort went into history (see Gordon, 1984). Some critical historians worked in the tradition of the social history of subordinated groups, using historical examples to show how ruling groups had used neutral- and equal-sounding legal doctrines to extend and justify their rule. Horwitz (1977) showed how early-nineteenth-century law had reworked private law rules of property, tort, and contract to favor entrepreneurs in the early nineteenth century, then later froze the new rules against redistributive revision by imposing constitutional restraints on legislation. Klare (1978) showed how conservative judges had drained the National Labor Relations (Wagner) Act of the New Deal of its potential as a charter of workers' rights to participate in management. Critical historians often read the past as a repository of lost social experiments, long since crushed or forgotten, which might serve as models for reconstructing aspects of social life – as did Frug with the nineteenth-century model of powerful autonomous city governments (Frug, 1980), and Simon did with 'social-republican' property models of landholding and producers' cooperatives (Simon, 1991). Other histories explored the legal structuration of social relations, especially those of master and slave, employer and employee, husband and wife (see, e.g., Steinfeld, 1991; Olsen, 1983).

By the mid-1980s CLS had entered a new phase. One group of critics, perhaps responding to accusations that CLS was 'nihilist' in its attachment to destructive criticism ('trashing'), turned to concrete programmatic work. Unger's (1998) was once again the most ambitious, proposing large-scale programs for the democratization of the economies of both developed and developing societies; most others were small-scale proposals for reforming specific legal policy fields, such as worker participation in ownership and management (Stone and van Wezel, 1988), treatment of workers in plant closings (Singer, 1988), regulation of injurious speech (Abel, 1994), intellectual property (Boyle, 1996), disability law (Kelman and Lester, 1997), and property rights in ex-Communist societies (Alexander and Skapska, 1994).

Another group focused on developing critical theories of law to a new level of sophistication, integrating them with postmodernist and poststructuralist theories, especially those of Foucault and Derrida (see, e.g., Balkin, 1987; Heller, 1984; Peller, 1985).

Challenges and Erosion

Around the same time, CLS experienced intensifying challenges from neighboring left legal-intellectual movements, especially feminism and critical race theory. The new movements asserted differences from CLS in focus and method – differences that provoked vigorous arguments throughout the 1990s. CLS had criticized liberal legalism for its claims to have solved the problem of domination by constructing 'rights.' Some critics said rights increased the alienation of individuals by constituting them as monads isolated from one another (Gabel, 1984). Others argued that rights mystified the realities of power relations, while still others argued that social movements' crusades for rights (such as the black civil rights movement) often ended up giving them only symbolic victories and unenforceable claims still others contended that rights, like other legal doctrines and policies, were always in conflict – the right to equal treatment in accommodations, housing, and employment, for example, with the right to associate – and that the conflicts could not be resolved by appeals to rights (Tushnet, 1984). Race theorists (e.g., Crenshaw, 1988) counterargued that whatever might be the weaknesses of rights-rhetoric, claims using the language of rights had been essential to the gains of subordinated groups. CLS scholars had also stressed the indeterminacy, manipulability, and contingency of social arrangements and legal discourses, the fluidity of meanings and identities. Some feminist and critical-race theorists, by contrast, wished to insist at least provisionally on the grounded objectivity of experiences of subordination, the common shared elements that made up sexual or racial identity and the authenticity of personal narratives of the lives of the subordinated (*see* Critical Race Theory; Feminist Legal Theory).

CLS had helped to open up and to institutionalize space – in the form of places for faculty positions, room for articles in law reviews, slots on the programs of conferences – for a legal-academic left, a novel phenomenon in the USA (and wholly missing in other professional faculties such as business schools). By the end of the 1990s, however, most of that space, like most of the energy going into novel work, was occupied by gender and race studies. CLS ideas continued diffusely to pervade both mainstream and critical fields of scholarship and policy analysis – notably its critiques of the public-private distinction and of the legal foundations of neo-liberal political economy. But as a distinct school CLS had faded away.

European CLS

European critical schools of law followed similar paths, with important differences due to national variations in the strength and programs of left-wing political parties and intelligentsia, and the objects of critique – traditional modes of legal training and reasoning – on the other. (A European Conference on Critical Legal Studies was organized in 1981.) In Britain, CLS were first concentrated in social science faculties and grew out of the radical sociology of law, oriented in its early years to the critique of the 'State' and its legal controls of poor and working people through labor, policing, criminal law, and professionalized social services, later evolving into broader critiques of law as ideology (see, e.g., Cain and Hunt, 1979). In the 1980s CLS was taken up by law teachers, especially in the polytechnics. They organized the Critical Legal Conference in 1984, proclaiming "a shared rejection of the dominant tradition of Anglo-American legal scholarship, the expository orthodoxy or … 'black-letter law' tradition" (Fitzpatrick and Hunt, 1987, p. 1). Believing that their American counterparts focused too narrowly on the internal critique of legal doctrine and reasoning, British critics maintained their connections to socio-legal studies and to radical law practices; they also developed new alliances with feminist, deconstructionist, psychoanalytic, and literary approaches. CLS in the UK, as in the USA, are a very fragmented enterprise, but unlike its American counterpart, it is flourishing (for exemplary collections and overviews see Fitzpatrick and Hunt, 1987; Douzinas et al., 1994).

In France the combined influence of (1) Marxist traditions treating law as 'merely superstructural' and (2) separation of faculties of legal philosophy and theory from faculties of law, held back the development of left-wing legal studies until the late 1960s, when radical social movements and the surge of interest in the social theories of Althusser, Gramsci, and Foucault led to critiques of law as forms of ideology that structure and legitimate the functioning of capitalist order. After the 1980s the movement shifted emphasis from general theory to concrete case studies of the norms, reasoning modes, and institutions that went into the construction of everyday legal relations. French CLS has not deeply penetrated the centers of university training of the legal elite, but has gained a foothold in some faculties and in research centers at St. Etienne, Lyon, and Montpellier (see Arnaud, 1993 for a concise summary).

Critical Planning Theory

Michael Gunder, University of Auckland, Auckland, New Zealand

Abstract

This article appraises the evolving nature of critical planning theory. It begins with an interrogation of critical planning theory derived from political economy. It then considers liberal pragmatic theory, followed by poststructuralist critical theory. This is followed by an examination of the contemporary range of critical critiques of the role of planning under neoliberalism. The article will conclude with a brief consideration as to why critical planning theory has continued for over four decades to provide an important ethical compass for the planning discipline.

Introduction

Planning theory may be conceptualized broadly under a contemporary triplet of labels: rational, communicative, and critical, which corresponds loosely to a topology of planning theory addressing three normative issues: 'What is planning's purpose?', 'What constitutes good planning process?' and 'What constitutes good planning?' (Yiftachel, 1989: p. 26). This article is principally concerned about the latter question. Critical planning theory (CPT) engages with questions of power, equity, language, knowledge construction, and related issues so as to test "professional concepts, models and 'gospels' against their real world material and discursive consequences" (Yiftachel and Huxley, 2000: p. 910).

Spatial and related types of planning, by their very nature, are largely apparatus of state government and governance (*see* Planning Theory: The Good City and Its Governance); hence, CPT inherently tends to interrogate the role of the state and its overarching constituting ideology to evaluate who benefits and loses through the application of planning's diverse activities. CPT might be further deconstructed under a range of categories attributable to the diverse fields of thought that have been applied to its theorization over the last several decades. Vastly simplified and aggregated, these include structuralist political economy, liberal pragmatism, poststructuralism, as well as a range of interrelated contemporary critiques of neoliberalism, with this last category largely emerging in the new millennium and yet to effectively formulate a singular overarching definitive label. This article will briefly consider separately each of these categories of thought, which have sequentially evolved over the last four decades in CPT, even though, in actuality, they often tend to overlap in their application and blur in their temporality. The article will then conclude with a consideration as to why CPT has continued to evolve over this period and suggest that this is because it provides an important and necessary ethical consciousness for planning that helps to provide a reflective "humanist philosophy to guide planners in their work" (Friedmann, 2008: p. 255).

Structuralist Political Economy Interrogation

Arising out of the popular dissatisfaction with Western governments of the late 1960s, and often drawing on the Marxist and at times contradictory positions of Manuel Castells (1977) and Henri Lefevbre (1991[[1974]], 1996, 2003[[1970]]), CPT, particularly in North America, drew on structuralist political economy to interrogate planning's role of facilitating the state and called in its day for a new revolutionary urbanism predicated on social justice (Harvey, 2009[1973]). Scott and Roweis (1977: p. 1099) best summarized this critical position for many theorists, by deploying Marxian critique to explain "urban planning as an observable social and historical phenomenon." In doing so, the two authors critiqued "noncritical" planning theory's underlying purpose, which they argued served and largely justified "the ideological and apologetic functions" of planning practice necessary to justify state interventions in capitalist "social and property relations" (p. 1114), while constituting a naive idealist-utopian urban problematic, which then calls out for a humanistic prescribe of what "*ought* to be" (pp. 1116–1117).

David Harvey (1985: p. 177) further engaged with critical political economy to argue that planners indeed shape and operate under a "progressive ideology" that purports to maintain a balance in society, predicated on rationality, in regard to the built environment so as to "reduce civil strife and to maintain the requisite conditions for the steady accumulation of capital" and this is achieved by placing the planner in the role of "defender of the public interest." Of course, what goes unstated in this progressive ideology is that the ultimate public interest is the creation of wealth, but not its equitable distribution. In this regard, Peter Marcuse (1976: p. 272) had a decade before being called for a structural approach to planning ethics, where planning "ethics could logically deal with issues of power and act directly to further values such as equity and democracy." Norman and Susan Fainstein (1979: p. 399) argued from this ethical perspective for the value of a working-class orientated planning practice that could "show the consequences for the lower classes of solutions proposed by monopoly capital" and which could create sensitive planning "solutions which address systemic problems … with minimal harm to the lower classes" so as to "advance working class interests."

Liberal Pragmatic Interrogation

Not all critical planning theorists of that period based their approach purely on structuralist political economy; many took

a more pragmatic liberal approach, all-be-it often influenced by the critical communicative theory of the German sociologist Jürgen Habermas (Forester, 1980). John Forester (1982: p. 76), following both Habermas and Lukes (2005[1974]), considered three types of mechanisms for exercising power in planning-related matters: through "[1] the ability to prevail in decision making…[2] the setting of agendas…[3] the ability of major institutions and actors to shape the felt needs and self-conceptions of citizens: for example, that they must acquiesce in the face of big government and big business…that individual market consumption will provide for the satisfaction of all needs, and that collective action is not a public responsibility but a nuisance." Taking an ethnographic approach to researching American planning practice, Forester (1989) found that practitioners often act in opposition to dominant power interests and he documented the planner's often attention-shaping role in seeking to resist domination so as to achieve more equitable planning outcomes.

Susan Fainstein (2000: p. 468, 2010), subsequent to her earlier pro-Marxist engagement, developed a liberal argument during the 1990s and 2000s for 'the just city,' one with an entrepreneurial state projecting 'a future embodying a middle-class society.' Fainstein (2010) established three interlinked criteria, or primary qualities constituting urban justice, for adjudicating the just city. These were 'democracy' and 'equity,' drawn from the American liberal perspective, and, attributed to poststructuralism, rather than liberal identity politics, that of 'diversity.' The author developed a list of principles for the furtherance of these three criteria, which were largely focused on planning for a more equitable American city, but one that used the European city of Amsterdam as its template. These ranged from prescriptive and detailed principles for the provision of affordable housing and public transit, public space provision, employee rights, through to calls for increased meaningful public consultation, consistent with the liberal-democratic American political tradition. The work called for more regulation and public ownership of resources, particularly by local government, while still operating within a capitalist market. Throughout her work, Fainstein has always argued for planners to help shift the urban problematic toward a greater concern for social equity.

With less optimism, Oren Yiftachel (1995a,b) explored planning's use as a state mechanism of society control, not for positive societal reform, but for the domination of a minority population. This was a use of planning that was not enlightened, but rather oppressive – hence planning's 'dark side'– and he empirically documented how state planning processes were deployed to spatially, procedurally, and socioeconomically oppress the Arab minority in the deeply divided society of Israel. Yiftachels (1998: p. 399) then universalized this critique and considered further "the dialectical tension between reform and control" by including a fourth dimension of potential oppression, implicitly, but not explicitly, categorized in the prior works: planning's potential cultural impact on minority groups in any society.

Bent Flyvbjerg (1996) also explored the 'dark side' of planning through his critique of normative idealism in modern social science and his development of an in-depth case study methodology, which he labeled phronetic social science. This was a social science approach that drew on the Aristotelian intellectual virtue of *phronesis*, so as to provide a method of social enquiry "to carry out analyses and interpretations of the status of values and interests in society aimed at social commentary and social action" that evaluates if particular public policies, such as a plan, are desirable and also determines "who gains and who loses" as a consequence and "by which mechanisms of power" (Flyvbjerg, 2001: p. 60). This is a CPT methodology that he deployed in his book-length critique of planning practice in Aalsbourg, Denmark, which clearly illustrated how dominant power was deployed in a Foucauldian manner to shape urban rationality (1998a).

Poststructural Interrogation

As well as Flyvbjerg, a number of other CPT authors placed Foucauldian analysis at the center of their CPT research. They ask the key critical question 'what is actually done' so as to provide necessary understanding and guidance to develop the 'strategies and tactics needed' to counter existing oppression and/or power imbalances, rather than the normative idealist question of much non-CPT of simply 'what should be done' (Flyvbjerg and Richardson, 2002: p. 61). Foucault, with his focus on power, is the predominant poststructuralist deployed for this critique, although others such as Derrida, Lacan, and Deleuze have also been called upon (Gunder and Hillier, 2009). Tim Richardson (1996: p. 280) introduced Foucauldian critique to planning theory as a set of tools to analyze the agonistic "dynamics of power and knowledge in policy making," so as to unmask power by grasping how "power appropriates knowledge, and weaves it into discourses" in the achievement of particular objectives. Richardson's discourse analysis sought to "ask how, why and by who, truth is attributed to particular arguments and not to others" (p. 283). He suggested that this Foucauldian approach allowed a new critical perspective from which to interrogate planning policy formulation by asking "how arguments are transformed into 'knowledge'" and that this perspective could form "an agenda of unmasking and challenging power, and the consequent empowering of excluded or weak minorities" (p. 290).

Unsurprisingly, several authors deployed poststructural critique to demonstrate the inherent failure of Habermasian-derived communicative planning, which had emerged in the 1990s as a prominent form of planning process concerned with participatory consensual decision making (Healey, 1992; Innes, 1995), to adequately deal with and engage with the concept of power. In this regard, Fischler (2000: p. 362) raised concerns about what Foucault called governmentality, that is, "the modern rationality of government—by revealing the origins of the ways in which people govern themselves, govern other individuals, and govern society at large" and cautioned that "we ought to think critically about communicative theory as a new theory of government and about collaborative action as a new form of governmental action." In contrast to a Habermasian seeking of utopian consensus, Flyvbjerg (1998b) drew on Foucault to argue for the importance of conflict to ensure democratic process, for from a Foucauldian perspective the suppression of conflict is also the suppression of personal choice for difference and the freedom to argue for

this choice. Perhaps the most critical nail in the coffin of communicative planning, at least from a poststructuralist perspective, was not derived from Foucault, but from Lacan. Hillier (2003: p. 46), drawing on Lacan, demonstrated how the very incompleteness and ambiguity of language makes the idea of consensus an impossibility, as "[t]here is always an excess of meaning that eludes representation."

Foucault's concept of governmentality has been deployed by several CPT authors in addition to Fischler. Gunder and Mouat (2002) demonstrated how governmentality was deployed in a manner "generating domination and oppression for the majority of the population within planning processes in New Zealand by subtle accumulations of minor manipulations, or pragmatic administrative practices of government, resulting in an aggregate of symbolic violence and the frustration of institutional victimization for the majority." Huxley (2002) explored the "history of the present" that interrogated planning as a form of governmentality; that is, a 'conduct of conduct' evolved genealogically through the codification of the social sciences that structures our taken for granted, or normalized, use of space. This is a normalized use of space that simply reproduces 'gendered regimes of domination' that produce the normalized female subject of 'compulsory heterosexuality, motherhood and reproduction' (p. 151). Consistent with Flyvbjerg (1998b), Pløger (2004: p. 73) also argued for resistance to mainstream planning "'governmentalities' framing urban governance initiatives and experiments" so as to engage with and respect the important role of strife and agonism in real-world planning practice. This was to positively empower local communities so as to ensure than planning actually created communities that are wanted by their inhabitants.

Contemporary Neoliberal Interrogation

Over the last decades, CPT's interrogation of planning has changed significantly as the postwar welfare state has evolved into the contemporary entrepreneurial neoliberal state. As outlined in the prior sections, "[s]ince the 1970s, the claims of planning to moral rightness, influence and expertise have come under scrutiny, with the result that the" traditional "legitimacy of the profession and public trust in its institutions have both been challenged" (Laurian, 2009: p. 369). Consistent with the dominance of the public choice school in economics and the rise of acceptance of neoliberal ideology, trust in bureaucratic planning prescription was eroded as an alternative to market solutions, with this arguably constricting 'the planner's role' to that of a 'designer of efficient and democratically acceptable market institutions' (Sager, 2009: p. 66).

Planning has come under further challenge as a consequence of a range of other, often related, issues. These include the challenge to "notions of exclusivity of knowledge"; the "displacement of the power of the bureau-professions by managerial [ism]"; the "de-professionalising tendencies of government through the imposition of performance management techniques"; and, not to mention, the "increasing specialisations within the domains of practice" (Vigar, 2012: p. 363). The latter includes the emergence of urban design, with its promarket/client orientation, as a new and separate profession to that of urban planning, which still tends to retain its orientation to achieve public rather than private goods (Gunder, 2011). Laurian (2009: p. 369) further asserts that planning has also come under challenge from an academic perspective derived from "the 'radical' critique of instrumental rationality and [planning's sometimes] monolithic, exclusive views of the public interest," as outlined in the prior sections.

Swain and Tait (2007: p. 236) contextualize planning in the context of modern risk society, where 'thick' trust of traditional expertise and authority is at best displaced into a 'thin' faith in expert systems. This was a consequence of an aggregate societal loss of individually perceived ontological security in the latter part of the twentieth century. This loss occurred as a consequence of heightened reflexive individual awareness that many issues of complex societal and planning concern, such as that of race, gender, or environmental risk, where not being adequately addressed by government, or other societal institutions (Beck, 1992). These were often concerns of great complexity, in contrast to the more 'manageable' concerns of traditional instrumentalist planning, where readily calculable best means could generally be determined to achieve measurably successful end states, such as the best means to calculate and then allocate vacant land necessary to meet forecast housing needs.

These new concerns were often 'wicked problems' (Ritter and Webber, 1973: p. 160) without readily calculable best means of solution or, in some cases, even fully comprehensible issues capable of having definable end states of resolution; hence, these wicked problems were not solvable, 'at best they are only re-solved – over and over again.' Accordingly, traditional prescriptive planning, predicated on instrumental rationality, was perceived to fail in this resolution of complex problems. In some instances, such as that of the United Kingdom, this gave ground to new planning approaches, predicated on communicative rationality (Gunn and Vigar, 2012). Yet, more often and more progressively over time, direct planning 'rational' prescription was simply displaced from the agenda, leaving ground for only market-driven issues and their market-driven 'solutions,' with difficult nonmarket-orientated problems largely displaced from the governance agenda, or, at best, they were dealt with in a nonspecific and generally meaningless 'feel good' manner (Allmendinger and Haughton, 2010: p. 804).

In this light, Sager (2009: p. 65) contends that under the global dominance of neoliberal ideology in recent years, New Public Management has become the "most important economic-political influence" on public sector institutional behavior and that this has transformed "the planning bureaucracies of many countries in line with principles of competitiveness, market-orientation, and economic accountability." In this context, the planner's role is perceived "as providing expertise in substantive and legal-procedural matters," with planned solutions being "in harmony with the market… thus leaving less room for politics" (Sager, 2009: p. 66). Further, this new planning practice also did not necessarily attempt to resolve 'wicked problems,' but often tends to obscure them, or, at best, give the appearance that something is being done – or managed – about them. This most often occurs by labeling these issues or solutions in desirous, but ultimately meaningless terms, such as sustainability, livability, resilience, or 'smart growth' (Gunder and Hillier, 2009).

Recent trends in the neoliberal turn of governance have resulted in a "managerial restructuring of government [which] has aimed at depoliticizing decisions by making them a matter of operational management…[where] [s]ocial and political issues are reduced to technical and procedural matters; they are translated into problems to be managed" (Sager, 2009: p. 73). Indeed, planning "has long stood accused of acting as a mechanism for depoliticisation, masking value-based decisions in rational—technical or professional justifications as a means of defusing conflict and imposing development without fully examining its social or environmental consequences" (Inch, 2012a: p. 523). Moreover, the communicative turn in planning's seeking of consensus further depoliticized contentious issues, as the "cooperative search for shared understanding and agreement cannot foster the kind of counter-hegemonic politics we require to challenge neoliberalization" (Purcell, 2009: p. 152).

This depoliticizing role of planning is often attributed to what has emerged in the last decade under the label spatial planning. Most commentators agree that 'spatial planning,' while comprising a wide range of diverse practices, is predominantly "predicated upon a role for planning of shaping economic, social, cultural, and ecological dimensions of society through 'place making'," with it generally having the characteristics of "encouraging long term strategic visions; providing the spatial dimension to improving integration across a range of sectoral plans and activity; supporting 'balanced' approaches to sustainable development; and improving engagement with stakeholders and the public" (Allmendinger and Haughton, 2010: p. 803).

Yet, Allmendinger and Haughton (2010: p. 804) go further and are critical of spatial planning, suggesting that spatial planning in its postideological, or postpolitical condition, is largely "organised around loosely defined and hard to refute 'feel good' issues and labels such as 'sustainable development'" that tend to promote "the use of consensus-based approaches to reinforce mainstream growth-led ideologies," which "in effect deny legitimacy and influence to more radical alternatives" and marginalize effective opposition. They continue (p. 809): "[f]ar from being strategic and steering, spatial planning could just as easily be portrayed as supine and subservient to powerful vested interests in the development process." Indeed, consistent with Fischler's (2000) concerns about communicative planning creating the grounds for a new form of governmentality, these authors go so far as to assert that "spatial planning…needs to be analysed as a form of neoliberal spatial governance" (Allmendinger and Haughton, 2012: p. 89).

In this regard, "[t]he problematisation of the planning system itself can therefore be seen as a means of covering over the underlying causes of conflict with fantasies of consensus that a fit-for-purpose planning process will create" (Inch, 2012a: p. 532). Indeed, a number of authors have documented, at least in the United Kingdom, that planning itself, or at least the prevailing planning system, has often been portrait in the role of scapegoat for both the state and the media when difficult to resolve contradictions occur between spatial activities, such as that of countryside housing provision, especially in the south of England (Inch, 2012a).

In professional planning practice, the "authenticity of knowledge circulating…is insured by the presence of professional standards" (Amin and Roberts, 2008: p. 359). However, within such communities of professional practice innovation "tends to be incremental rather than radical," where "the protectionist role of professional associations can act as a barrier to radical change" with at best professional associations promoting the dissemination "of new incremental knowledge across the sector" (Amin and Roberts, 2008: p. 359). Further, as the following authors contend, this institutional professional barrier to radical change actually facilitates the adoption of planning practice that tends to conform to the values of the dominant actors shaping the *doxa* of contemporary society. Further, this conformist practice generally fails to engage with unresolvable, or wicked problems, rather its consensus-based approach tends to, at best, paper over these difficult to resolve concerns and issues and concentrate on what really matters: market success and resultant economic growth.

While Amin and Roberts (2008) argue that the protectionist role of professional planning associations tend to act as a barrier to significant planning change, Andy Inch (2012b) documents how British planners, led by their professional institute – the Royal Town Planning Institute – sought to redefine, or reterritorialize, their professional practice during the first decade of the new millennium, as 'spatial planning,' rather than the more traditional 'land-use planning' or 'town planning.' This *cultural work*, as Inch (2012b: p. 528) calls it, required the profession "to reshape the knowledge, social relations and identities underpinning their practices, organising the attention of other actors, and altering existing conceptions of planning's role" resulting "in reworking the boundaries of the field of professional practice, at various levels from the national to the local."

This process was also co-opted in the interests of the state and used as a mechanism to further facilitate planning as a largely postpolitical process (Allmendinger and Haughton, 2012). Indeed, rather than increasing and empowering the discretionary professional space for effective planning practice, some contend that the adoption of a spatial planning paradigm has actually reduced it (Gunn and Vigar, 2012).

Yet, planning is still often perceived as making a positive contribution to society. But this is because today's successful planners are often empowered by market success, that is, they are seen as contributing to the neoliberal success of their polity. In this light, "[c]ontributing to the overall 'gain' for the city, to the 'good' for the city, as defined by neoliberal planning principles, acts as an aphrodisiac for planners and other policy makers, since those principles form the parameters of urban success" (Baeten, 2011: p. 209). That these principles and the plans and projects that they often create have a tendency to negate anything that does not contribute to economic gain is just not part of the consideration (Gunder, 2006).

Indeed, within the neoliberal world of the new millennium, the traditional authority and disciplinary rules of government and that of its planning experts providing public welfare have been displaced. Rather than traditional government facilitating a role of pastoral care for its Foucauldian docile and obedient population in creating a 'better' world for all, a new ideal has emerged of the state facilitating socially mobile competitive individualism. As a consequence, the "*symbolic* prohibitive

norms" of the welfare state have been "increasing replaced with *imaginary* ideals (of social success," of smart growth, of livability, of sustainable development – which Swyngedouw (2010) refers to as the new opiate of the masses – not to mention, being a globally competitive city to ensure wealth creation), where the neoliberal subject is actually driven by a societally imposed injunction to no longer simply 'obey' but rather to ultimately 'enjoy' in his/her 'sustainable' consumption (Žižek, 1998: p. 480 – emphasis in original). This contemporary world is no longer simply a world of government, but rather one of governance, and the ideological role, or appearance, of planning is no longer one of control so as to channel balanced development for a collective public interest, but rather to facilitate the success of a polity by ensuring the appropriate environment for the competitively achieved market-derived enjoyment for its residents (Gunder, 2010). Planning's contemporary mainstream success is largely adjudicated accordingly. Consequently, CPT's contemporary task now is to open this adjudication to challenge where and as necessary.

The Importance of CPT

A small group of planning theorists and related scholars have asked critical questions of planning and planning's role in wider society over, at least, the last four decades. Their arguments and debates have been derived from a range of schools of thought, but generally they have been concerned about equity, fairness and social justice. They have all interrogated the role of planning as an agent of the state facilitating public policy as to how the future city should be constituted. CPT has endured because it provides an important and necessary ethical consciousness that questions planning practice so as to help provide a reflective "humanist philosophy to guide planners in their work" (Friedmann, 2008: p. 255). Indeed, CPT repeatedly reminds planners for the need to continuously reflect on how power is deployed both by others and by their own practice on and in their communities and throughout wider society.

CPT has sought to remove the ideological veils that shield and shape the mechanisms that drive the capitalist global culture forward and that often induce distortions and disparities within and across societies. Indeed, planning is largely about trying to change the way things are for something better, which is inherently a normative task. These good ideas of how to achieve a better future community are highly subject to capture by the powerful in the seeking of their own interests. CPT is also an important and necessary check and balance on planning practice itself. It provides a means to understand what is actually being done, who actually benefits, and who may actually loose. With this questioning and resultant understanding comes the potential to develop tactics and strategies that may make planning a more equitable process that indeed can lead to more effective planning practice, and potentially better communities for all inhabitants; however, each polity may wish to collectively define its normative concept of 'better.'

Critical Psychology

Abstract

During the student revolts in the late 1960s arose the requests for a leftist critique of so-called bourgeois psychology and for the construction of a new psychology in the service of the repressed proletariat, repressed women, and repressed ex-colonial peoples. High hopes were set on Marxism as the basis for both objectives, especially of the kind developed by the Frankfurt School. Various alternatives of psychology that followed a Marxist model came to be known under the term 'critical psychology.' The most prominent school of critical psychology originated in West Berlin under the leadership of Klaus Holzkamp. They adopted the Soviet modification of Marxism, Marxism–Leninism including historical and dialectical materialism, as their basis for what became known as Critical Psychology, capitalized. There are still other critical currents in psychology calling themselves 'critical psychology,' generally, however, without such a definitive philosophical underpinning and such a comprehensive scope.

The term 'critical psychology' has been applied to various approaches to psychology which, in the last decades of the twentieth century, typically share hardly anything more than a resistance to so-called 'mainstream or traditional psychology,' an affinity to the moral ingredient of the Marxist critique of capitalism, and an aspiration to fight for the oppressed and the excluded. The connection to Marxist thought was further mitigated in the twenty-first century.

Critical psychologies of whatever nuance are not connected to I. Kant's critical philosophy or to neo-Kantian approaches to psychology despite the fact that one of the authorities of critical psychology, S.L. Rubinshtein, started out as a student of neo-Kantianism in Marburg.

One division in the heterogenous stream of critical psychologies is named 'Critical Psychology.' This is a school of psychology that chose to spell its name with capital letters; it originated in the 1970s in West Berlin, and is centered in the work of K. Holzkamp. It describes itself as being Marxist–Leninist, scientific (in a Marxist sense), and critical of what it calls bourgeois psychology. Critical Psychology will be the primary object of this article as it is so far the branch of critical psychology with the most noticeable degree of social coherence and of theoretical consistency.

Origins and Early History of Critical Psychology

The second half of the 1960s witnessed a rapid increase in the university student population in the Western world. The resulting tension and uneasiness combined with the televised atrocities of the Vietnam War to produce an international agitation for global revolutionary changes in a world engaged in Cold War.

An important factor in the student revolt, especially in Germany, and also in the formation of critical psychology and Critical Psychology, was the Critical Theory of the Frankfurt School, a strain of Marxism embodied by T.W. Adorno, M. Horkheimer, H. Marcuse, and J. Habermas. Especially pertinent at universities was their critique of positivism in sociology and in other social sciences, and generally of positivism in the sciences as prominently advocated by K. Popper. The positivist emphasis on the priority of observable events and empirical data over hypothetical constructs and theoretical terms was criticized as a deceptive disguise for sinister theory, especially for reactionary ideology in the service of capitalism. Therefore, the key reproach against positivism was its presumed lack of scientific relevance and of relevance for social change.

The Frankfurt School itself was not interested in the academic discipline of psychology. But psychology students watched the positivism controversy and applied it to their own field. A student Action Committee Critical Psychology disturbed the customary serenity of the congress of the German Society for Psychology at Tübingen in 1968, and, in order to coordinate various local initiatives, students met for a singular and tumultuous Congress of Critical and Oppositional Psychology in Hanover in 1969.

The term 'critical psychology' appeared for the first time as a book title *Kritische psychologie* in 1969. This is an anthology compiled by Bochum University psychology students comprising pirated texts by T.W. Adorno, W. Reich, K. Holzkamp and others, and various resolutions exchanged at the Hanover Congress and at earlier occasions. Sold in many psychological institutes, it established the term as a trademark for revolt, and stepped up rebellious behavior which few university teachers could stomach. The concept of critical psychology covered a multitude of different convictions, from an engagement for the weak and the betterment of society, to the use of psychology in a Marxist class struggle, to the conviction that psychology is unredeemably reactionary and should be dumped on the dungheap of history. Views of the future of psychology varied accordingly.

Among the few university professors who engaged in extended dialog with critical psychology students was Klaus Holzkamp (1927–95), holder of a chair of psychology at West Berlin's Free University. He had, in 1964 and in 1968, published a critique of psychological experimentation wherein he denounced the lack of criteria for the evaluation of the relevance of psychological experiments for psychological theory. He tried to improve the diagnosed situation by following the constructivist philosophy of science of

H. Dingler, the most prominent European proponent of operationalism.

In an invited speech at the Berlin section of the German association of professional psychologists in I968, Holzkamp applied the concepts of technical and emancipatory relevance, which he had taken from J. Habermas, to psychology and declared emancipatory relevance superior to all other forms of relevance. Through his discussions with critical students, Holzkamp was introduced to an analysis of society and its dominance relations according to Marxist lines. In his collection of essays, *Critical Psychology* (Holzkamp, 1972), he called his change in outlook the *Critical-Emancipatory Turn of Psychology*. Activity at the West Berlin psychological institute was characterized by studies in the history of psychology, which strove to uncover its quality as a tool of oppression in the ongoing class struggle (Geuter and Mattes, 1984), and by practical engagement for the underprivileged. This approach to the practice of psychologists remained what Holzkamp later called 'voluntaristic,' that is, appealing to the good will of psychologists and a willful decision for partisanship for the weak and needy.

As the antiauthoritarian and nonconformist movement slowly became organized by political parties and splinter groups in the early 1970s, so were the critical psychologists at the psychological institute in West Berlin Free University. One faction drifted into the sphere of influence of the Marxist–Leninist party (SED) ruling East Germany (DDR) and its West Berlin vassal party (SEW); another faction gathered around Beijing-oriented Maoist lines; others become Trotskyites, while a good many remained nonaligned. The psychologists around Holzkamp enlisted in the Marxist–Leninist camp. They withdrew from dialog with other factions, fashioned their own publication outlets and, to emphasize their distinctness, from the middle of the 1970s spelled their field as Critical Psychology. This group has also been known as the Holzkamp School, or the Berlin critical psychologists, despite other critical psychologists protesting that it was merely one offshoot of a much broader critical psychology unjustifiably trying to usurp the appellation and to eclipse the other approaches. The Marxist–Leninist turn has led Critical Psychology indubitably away from Adorno, Critical Theory, and the New Left.

Creation of Capitalized Critical Psychology

Capitalized Critical Psychology defines itself as a Marxist–Leninist psychology (Holzkamp, 1983: p. 27). It looks toward the writings of K. Marx, F. Engels, and V.I. Lenin for orientation, and adopts as its scientific and epistemological foundation or superstructure dialectical materialism and historical materialism. It embraces as pioneering works in this kind of psychology the publications of the historicocultural approach devised during Stalin's reign by L.S. Vygotsky and his disciples, in particular, S.L. Rubinshtein and A.N. Leont'ev. These authors were *de rigueur* for prefaces to be considered ideologically impeccable in the psychology of the DDR and the USSR, even though few serious scientists paid more than lip service to the ideological superstructure.

Holzkamp's turn away from critical emancipatory psychology toward Critical Psychology became visible with his book on *Sensory Cognition* (1973), where K. Marx is the most often cited author, and *Das Kapital* provides the model of human consciousness as dependent on and determined by the material and historical foundation of economic and social practice. Traditional psychology, now named bourgeois psychology, however, is perceived as erroneously proclaiming the independence of consciousness from this material basis.

Critical Psychology had not only an ideological superstructure but also a rarely considered material basis as well, namely the chair of psychology at the Free University in West Berlin held by Holzkamp and the power and privileges that went with it. A German university professor is a civil servant, but at the same time enjoys a very high degree of academic freedom in research and in teaching, as guaranteed by the constitution. This freedom, however, may have one limitation. A professor of psychology is obliged to train and examine future psychologists according to the canon of the examination Regulations.

Critical psychology's critique of traditional or bourgeois psychology had purportedly unveiled the latter's theoretical hollowness and its practical use as a weapon of the ruling classes against the proletariat. This brought Holzkamp into a 'dilemma' (1973: p. 13). Either he could go on teaching and training in bourgeois psychology and thereby lose his credibility as a critical psychologist, or he could stop training psychologists altogether, limit himself to criticizing psychology, and face the loss of his professorship and its benefits. He resolved this 'fatal alternative' (1973: p. 15) in a way that he thought allowed him to preserve critical credibility and to keep the material basis as well. He devised Critical Psychology, a new brand of psychology professedly consistent with the results of the critique of traditional psychology and also suitable as a foundation for the training of future practical psychologists.

Holzkamp and his coworkers had to prove that Critical Psychology could deliver. They formed a secluded group and started out to present to the public the various areas of psychology mentioned in the Examination Regulations in a new fashion according to Critical Psychology.

Organization of the School of Critical Psychology

Critical Psychology organized itself as a school of psychology with defined teacher–pupil relations and clear boundaries between insiders and outsiders. Its center was the chair of psychology occupied by Holzkamp, who was surrounded by assistants, doctoral students, and students. The notable names are gathered in the reader *Critical Psychology* (Tolman and Maiers, 1991). The West Berlin case remained unique. Critical Psychology could never gain a similar foothold in another university institute.

A series of textbooks, *Texte zur Kritischen Psychologie*, started to appear in 1973. It was supplanted in 1977 by another series, *Studien zur Kritischen Psychologie*, which appeared in the publishing house of Marxist–Leninist orthodoxy. The journal *Forum Kritische Psychologie* began to appear irregularly in 1975, and was turned into a biannual journal in 1977. A congress of Critical Psychology was held in the West German university town of Marburg in 1977; further congresses, now named

'International,' were held there in 1979 and 1984, and a fourth congress, not 'International,' in Berlin in 1997.

The 1980 and 1990s seem to have been a time of stagnation for Critical Psychology. But steps were undertaken to introduce an international public to Critical Psychology (Tolman and Maiers, 1991; Tolman, 1994).

In the 2010s, Critical Psychology is still taught at some places. The Psychological Institute at the Berlin Free University harbored until recently a subdivision for *Research on the Subject and Critical Psychology*, and still has a *Klaus Holzkamp Institute for the Science of the Subject.* Holzkamp is respected as the founding father of Critical Psychology, and an at-present unfinished edition of his *Collected Works* (*Schriften*) in seven volumes is in preparation at the *Institute for Critical Theory* (Holzkamp, 1997, etc.). His *Grundlegung der Psychologie* (*Foundation of Psychology*, Holzkamp,1983) is considered authoritative in the field, and in order to enhance the reader's understanding of his cloudy prose, a separate introduction into the matter has been published (Meretz, 2012). The latest developments may be followed at www.critical-psychology.de or www.kritische-psychologie.de.

Themes and Topics of Critical Psychology

Critique not only has to scrutinize the 'bourgois' or mainstream psychology but also must reflect the subject matters of psychological research, because these are not unconditional givens, but are the products of the economical and societal conditions under which individuals come into being and are formed.

Work done in Critical Psychology is to an uncommon degree conceptual work. Basic categories of psychology are put under scrutiny in the so-called functional-historical analysis of categories with the aim of reconstructing them under more satisfactory conditions. Psychological categories (or rather what they contain), like perception, motivation, learning, emotion, and cognition, are considered in their phylogenic, historical, and ontogenic evolution. At the end of this process, newly defined or rehabilitated categories are offered for the construction of an encompassing system of psychology.

Functional-historical analysis blends two things. One is C. Darwin's theory of evolution. It is utilized mainly for armchair paleozoology and paleoanthropology, and amplified and revised by the other constituent, Hegelian dialectics in its specific modification formulated by K. Marx, F. Engels, and later luminaries of Dialectical Materialism like G.V. Plekhanov. Functional-historical analysis, therefore, includes controversial Marxist tools of thought like negation in nonconceptual matters (antithesis), contradiction as causal agent (thesis–antithesis clash), or qualitative leaps or transitions (resulting in syntheses as unities of opposites, and forming the new theses for more dialectics). Such qualitative leaps are, among others, the transition from prepsychical to psychical organisms, the differentiation of special psychical functions, the evolution of learning, and the emergence of the societal nature of human beings.

These tools of thought are usually disregarded in science. It is therefore difficult for the reader not trained in their applications to follow the train of cogitations in which they are used. It is also not feasible to paraphrase them adequately in non-dialectical prose, and therefore, it may be fitting to let Critical Psychology speak for itself. This is a summary of the five steps of the functional-historical method according to Holzkamp (1983: p. 78):

1. Identify the real historical dimensions within the preceding developmental stage of the organism at which the quantitative transformation in question took place; that is, determine the 'position' that is dialectically 'negated' by the qualitative transformation and thereby bring the specificity of the new developmental stage into relief.
2. Identify in the external conditions the objective alterations that constitute the 'environmental pole' of the inner developmental contradiction that causes the new quality to emerge. Such alternations involve a 'moderate discrepancy' that, on one hand, demands 'compensations' from the organismic system, yet is supportable within its capacity. If it is not, the overall organism–environment system collapses, the inner contradiction is turned into an external opposition, and its antipodes will no longer be mediated as 'poles' in further development.
3. Identify the change in function of the relevant dimension demonstrated in Step 1 as the 'organism pole' of the developmental contradiction and with it the origin of the first qualitative leap, that is, the development of the specificity of the new function under the altered conditions. This dialectical negation of a previously prevalent function does not determine the overall process but, in a sense, still serves to maintain the system at the earlier stage.
4. Identify the change of dominance between the earlier function characteristic of the system's maintenance and the new function, which then determines the specifics of the system. (This change presents itself as a discontinuous reversal of the relationship between two continuously changing dimensions.)
5. Identify the ways in which the overall development of the system is restructured and assumes new direction (that is, analyze the 'specific secondary alterations,' and so on) after the qualitatively more specific function has become determining for the system's maintenance. With this identification of the qualitatively new dimensional structure, in which further qualitative transformations will occur, follows a return to the first step of the analysis but at a higher level (Tolman and Maiers, 1991: p. 39f.).

Categorical analysis leads to three characteristics of the human societal mode of existence: action possibility, action potency, and subjective situation. The latter is a personal assessment of one's own action possibilities and of where one stands in a particular objective situation. This derivation leads to a novel understanding of subjectivity and of the famous quote from Marx, "The essence of man is conscious activity."

In personality psychology and psychotherapy, Critical Psychology tries to utilize Freudian psychoanalysis. After a deft functional-historical analysis of its categories and of the fumbling efforts of Freudo-Marxists, it presents itself as the Marxist alternative to psychoanalysis.

The enthusiasm of early critical psychology to investigate the history and function of psychology is not followed by Critical Psychology. There is no critical historical analysis of the

fate of psychology and psychologists in the USSR, especially during the times of Stalinism and anticosmopolitanism when Vygotsky initiated the historicocultural approach, and Rubinshtein and Leont'ev became its proponents. Nor is the practical application of psychology in the USSR or DDR, particularly in their armed forces and secret services, examined.

Critique of Critical Psychology

There have been numerous controversies around Critical Psychology, among them the following.

Holzkamp and the not-yet capitalized critical psychology came under attack by H. Albert and others (Albert and Keuth, 1973), who championed a Popperian position for psychology and the social sciences. The ensuing debate in psychology reiterated the main positions of the positivism controversy between Popper and the Frankfurt School.

Holzkamp's turn to Critical Psychology and the associated Marxist–Leninist position provoked the criticism of other tendencies in the spectrum of critical psychology. This resulted in a number of more or less ephemeral publications, the most accessible of which is edited by Busch et al. (1979). Points of criticism were the usurpation of the name 'critical psychology,' the political orientation on Marxist–Leninist lines, and a perceived retrocession to bourgeois conceptions of psychology.

Disapproval of Critical Psychology by psychologists working in the DDR could not be uttered before the collapse of Real Socialism and the Soviet empire. But then they could report that they felt a virulent distaste for it as DDR party officials reprimanded their local psychologists for staying aloof from party doctrine and advised them unpleasantly to follow the ideologically blameless example of Critical Psychologists.

Other Critical Psychologies

It is not appropriate to call Critical Psychology 'German critical psychology,' as T. Teo (1998) does. There are and always have been other critical psychologists in Germany who have no affiliations with Critical Psychology. They gathered around the journal *Psychologie und Gesellschaft*, which was established in 1977 and renamed *Psychologie und Gesellschaftskritik* in 1978. Rexilius (1988) assembled some of the nonaligned voices.

An early voice in critical psychology was that of Peter Brückner (1922–82). From 1967, he occupied the chair of psychology at the Technical University in Hanover. There was no professional training of psychologists. Brückner did not publish systematic treatises on his view of psychology or on standard examination topics, but he authored a *Social Psychology of Capitalism* (1972), and papers on political psychology and on psychoanalysis (1983). Although he had some disciples, they did not organize a school.

A comparative portrayal of three early critical psychologies, Vygotsky's, Holzkamp's, and K.F. Riegel's dialectical psychology, was published by Ijzendoorn et al. (1984).

Another kind of critical psychology arose at Salzburg, Austria, in the footsteps of Igor Caruso. It attempts to eventually combine Marxism and Freudian psychoanalysis, an endeavor carried on by leaps and bounds since the 1920s, most prominently by Wilhelm Reich. The contemporary labor in this vast field is presented in a *Kritische Psychologie* (Abl, 2007), which is critical of Holzkamp's approach.

There is a tendency in English-speaking countries for various New Left tendencies to rally under the name of 'critical psychology.' Information on present trends may be found in Fox et al. (2009), Sloan (2000), the *Annual Review of Critical Psychology* (founded in 1999), the *International Journal of Critical Psychology* (2000 till 2008), continued in *Subjectivity, International Journal of Critical Psychology* (founded in 1986), and the *Journal of Critical Psychology, Counseling and Psychotherapy* (since 2001).

Concluding Remarks

At present, three hardly compatible currents that make use of the expression 'critical psychology' may be observed.

There is the capitalized Critical Psychology created by Holzkamp. Its trademark is the application of the Marxist–Leninist conceptual toolbox of dialectical and historical materialism described above. Its established introductory textbook is the *Introduction into Critical psychology* by M. Markard (2012), now in its fifth edition.

There is a less circumscribed critical psychology that is carried by a consensus that a Marxist inspired moral critique of capitalist societies, sporadically combined with the moral portion of Lenin's critique of imperialism, could bring about a psychology for the betterment of the human condition. Here, the theoretical pillars of Marxism like the labor theory of value, the theory of class struggle as the motor of social change, the theory of the approaching collapse of capitalism, and dialectical and historical materialism seem to be have lost much of their plausibility and currency. Sometimes this current is called 'radical psychology,' voluntaristic impulses seem to rule, and constructivism and feminism are typical influences.

There is a nonspecific employment of the expression 'critical psychology' as an abbreviation for multifaceted criticism regarding the theories, methods, and the usefulness or social relevance of the science and the discipline of psychology. This type of critical psychology is to be found all over the globe in such diverse countries like Italy (Colucci and Montali, 2013), Japan (Igarashi et al., 2013), and Sri Lanka (Vithanapathirana, 2013) or Brazil (Lacerda, 2013). It is difficult not to generate the notion that any sensible psychologist in the history of psychology has already contributed her/his share of what this current calls critical psychology.

From what can be known at present about the not-yet published international fourth volume of *Encyclopedia of Critical Psychology* under the editorship of Teo (2014), it seems fair to regard it as a commixture of the second and the third currents of critical psychology.

The various versions and mutations of critical psychologies present worthwhile case-study material for research in the predicament of the discipline of psychology and the dialectics between psychology as a science and as a profession. When in the twentieth century psychology was hastily metamorphosed into a practical profession, the university institutes had to be converted from pure research institutions into training

establishments – and they had to somehow cope with the egregious gap between the high expectations of application-minded students and the comparatively limited amount of effective tools psychology had to offer. For some of the discontented, Marxism–Leninism or pure Marxism promised to be the answer for the twentieth century. In the twenty-first century, while still receptive to calling one's own stand 'critical,' these theoretical edifices seems to have lost much of their past appeal.

Critical Race Theory

Abstract

Critical race theory is a body of work that first emerged in American legal scholarship in the late 1980s and has since spread to other disciplines. It investigates a paradox: How does racism persist despite its nearly universal condemnation by state policy and by the norms of polite society? Rejecting the conventional liberal position that racism survives only as a relic from a less-enlightened time or as a characteristic of poorly educated or troubled individuals, critical race theorists take the position that racism is ordinary and normal in contemporary society, indeed perhaps integral to social practices and institutions.

Critical race theory investigates a paradox: How does racism persist despite its nearly universal condemnation by state policy and by the norms of polite society? Rejecting the conventional liberal position that racism survives only as a relic from a less-enlightened time or as a characteristic of poorly educated or troubled individuals, critical race theorists take the position that racism is ordinary and normal in contemporary society, indeed perhaps integral to social practices and institutions. Critical race theory can thus be understood as a study of hegemony: how domination can persist without coercion. It can also be understood as a study of collective denial.

Critical race theory originated in American legal studies during the post-Civil Rights Movement period, out of a sense of frustration that the era's 'Second Reconstruction' had failed to extirpate racism (see Crenshaw, 1988; Ansley, 1989). Its central target of critique has been state law, and its primary methodological innovations in legal scholarship have been the use of storytelling, fictional or anecdotal, to criticize legal reasoning and legal doctrine; and a method of reading against the grain that refuses to take legal doctrines at face value. Substantive themes of critical race theory in law include a sustained attack on the US Supreme Court's contemporary jurisprudence of race, particularly the position that the state can and should be colorblind; attempts to theorize unconscious racism or implicit bias as well as structural racism; the examination of race relations beyond the black/white paradigm; and efforts to understand how race interlocks with other forms of oppression. Future directions for critical race theory include its migration into and collaboration with other disciplines and scholarly fields, and an interest in placing US race relations into a global political-economic context.

In contemporary US social life, it is popularly accepted that racism is a form of injustice and that state law has the moral obligation not only to refrain from perpetrating racist acts against citizens but to provide redress for certain victims of nonstate racism as a matter of public policy. Most debates over antidiscrimination law and policy focus on the scope of these obligations. With respect to the state's obligation not to perpetrate racism itself, a question is whether antidiscrimination norms are satisfied when the state eschews all race-conscious state and nonstate public action, or whether the state should undertake race-conscious actions in certain circumstances in order to remedy its own past and continuing racial discrimination. With respect to the state's obligation to remedy nonstate discrimination, questions include to what extent the state should remedy private discrimination at all, and where the lines between public and private behavior should be drawn. These debates also require a definition of what 'discrimination' means.

Writers who associate themselves with critical race theory take the position that racism is ordinary and normal in American society (Delgado, 1994), indeed perhaps integral to it. Accordingly, critical race theorists attempt to show how contemporary law – including contemporary antidiscrimination law – paradoxically accommodates and even facilitates racism. The critical race theory project inevitably calls into question fundamental assumptions about legal institutions and legal reasoning, about the trajectory of American history, and about the nature of injustice.

One tendency within critical race theory, deriving from the tradition of civil rights activism and jurisprudence, is strongly reformist in bent and seeks to galvanize moral outrage and direct it toward constructive legal change. A second influence on critical race theory is the poststructuralist tradition, within which the very possibility of overcoming racism through discursive structures such as law is considered a false hope. Critical race theory thus reflects a distinctive mix of reformist zeal and critical pessimism (A. Harris, 1994). For example, Derrick Bell has urged civil rights activists to accept that, although there is a moral duty to challenge racism, racism is a permanent feature of American society (Bell, 1992). Other scholars influenced by critical race theory pursue the hope that innovations such as the theory of 'implicit bias' can successfully reshape antidiscrimination law into a more effective tool against racism (Kang et al., 2012).

Origins of Critical Race Theory

Critical race theory emerged in the United States in the 1980s as a product of political, intellectual, and sociological developments in American legal academia. Politically, the 1980s were a time when many American civil rights activists and left-wing legal scholars felt themselves caught up in a conservative backlash against the gains of the 1960s. The scholars who would later call themselves critical race theorists sought explanations for why formal legal equality had produced only

modest success in improving the lived experience of most African Americans and other people of color, and why hopes for social integration with whites seemed largely to have faded (Crenshaw, 1988; Ansley, 1989).

Intellectually, the early 1980s saw the heyday of critical legal studies (CLS) in the American legal academy. CLS introduced into legal scholarship poststructuralist ideas that had already permeated other disciplines focused on the interpretation of texts, including philosophy, literary criticism, and anthropology. Within legal studies, CLS scholars challenged the divide between law and politics, arguing that legal rules were radically indeterminate. CLS called for the deconstruction or trashing of legal doctrine in order to expose the reification of legal concepts and the hegemonic function of traditional legal reasoning (Kelman, 1987). CLS also provided an intellectual opening for broad-based critiques of law based on hidden norms of race and gender exclusion. For example, the first collection of essays in critical race theory appeared under the title *Minority Critiques of the Critical Legal Studies Movement*; its authors were CLS sympathizers who nonetheless were disappointed with CLS's failure to extensively engage with racism (Delgado, 1987; Williams, 1987).

Sociologically, the 1980s saw the gradual entry into legal academia of African Americans and other people of color, albeit in small numbers. Many of these new scholars were drawn to study race and the law, were frustrated by the disappointing outcomes of traditional avenues of legal reform in an era of backlash, and perceived traditional civil rights scholarship as a literature that ignored the voices of people of color (Delgado, 1984). Several key figures in what would become critical race theory were radicalized as students by the departure of Derrick Bell, one of the pioneering African American scholars critical of existing civil rights jurisprudence, from Harvard Law School because of its failure to hire an African American woman to the tenure-track faculty. These Harvard students created their own course on race, racism, and the law, and staffed it with visiting scholars from around the country. The movement known as *critical race theory*, and the term itself, emerged from this working group of students and teachers (Crenshaw et al., 1995).

Themes of Critical Race Theory

One of the earliest themes to appear within critical race theory was epistemological in nature and was reflected in a distinctive method. Why were people of color much more likely than whites to see American society as racist and to be pessimistic about the possibility of eliminating racism? Did they know something whites did not? Many critical race theorists argued that existing antidiscrimination law omitted the perspectives of the racially subordinated, and that subordinated groups in any social system have knowledge that the privileged lack. Thus, in a famous essay, Mari Matsuda argued that civil rights scholarship and practice should 'look to the bottom' of society for leadership and insight (Matsuda, 1987). Some scholars argued for the existence of a distinctive 'voice of color' that needed to be heard in public policy and legal scholarship (e.g., Johnson, 1991).

Critical race theorists also frequently abandoned the third-person objective voice in their legal writing in order to openly tell stories. For example, Derrick Bell's *Civil Rights Chronicles* featured an imaginary character who could travel through time and who used her magical powers to criticize American civil rights doctrine from the drafting of the Constitution to the present (Bell, 1985, 1992). The telling of personal anecdotes or fables was intended not only to convey ideas that could not be expressed in traditional scholarly language but also to criticize the assumption that norms of legal scholarship, legal reasoning, and legal institutions operated objectively and produced neutral assessments of public policy. Critical race theorists hoped to show that the legal scholar's 'perspectivelessness' (Crenshaw, 1989b) was in fact a perspective aligned with white privilege. Thus, for example, Patricia Williams, trained in poststructuralist theory and CLS, used personal stories, a dense web of allusions, and literary techniques to critique the social and legal construction of racial realities (P. Williams, 1991). The assertion of a distinctive voice of color proved controversial; critical race theory, like CLS before it, was bitterly attacked as racial 'special pleading' and as degrading the rigorous standards of argument and research established by traditional legal scholarship (see, for example, Kennedy, 1989). Legal storytelling was similarly attacked as sloppy scholarship and as an attempt to destroy the legacy of the Enlightenment. In this attack, critical race theory was taken to be a postmodernist assault on truth itself (see, for example, Farber and Sherry, 1997).

Drawing on the CLS tradition, critical race theorists have developed a distinctive style of reading against the grain, or, put another way, have adopted a hermeneutics of skepticism with respect to legal doctrine. This is often done by placing jurisprudential developments in a larger political and historical context in order to identify the continuity of racial oppression across time despite changing legal and political regimes. Thus, for example, Michelle Alexander argues that mass incarceration in the contemporary United States can properly be called 'the new Jim Crow' because it restricts the life chances of African Americans in the same way as *de jure* racial segregation in the pre-World War II South (Alexander, 2010). Ruth Gordon argues that the multilateral regime of the World Trade Organization has set sub-Saharan Africa up to remain poor and disorganized (Gordon, 2006). Derrick Bell argues that *Brown v. Board of Education*, the landmark constitutional case that struck down *de jure* segregation in elementary education, has become a historical artifact without contemporary significance given the resegregation of American schools (Bell, 2008). Critical race theorists thus set jurisprudence within a narrative of preservation through transformation – the idea that racism constantly changes in form but not effect (Siegel, 1997; see also Calmore, 1997). In this way, critical race theory represents a critique of the conventional liberal faith in social progress.

Most of the writing within critical race theory, however, has not taken on philosophical questions or even strayed very far from conventional methods of legal scholarship but rather has consisted of a sustained attack on the US Supreme Court's race jurisprudence, particularly its constitutional jurisprudence. For example, as one scholar has it, throughout the 1980s and 1990s the Court asserted its fidelity to four constitutional traditions

(Hayman Jr., 1995). First, the Court increasingly favored a position of colorblindness, under which all government racial classifications are presumptively unconstitutional, except perhaps when necessary to compensate a group of plaintiffs who can demonstrate the existence of conscious, deliberate racial bigotry that caused material disadvantage. Second, the Court frequently deferred to legislatures, to state and local governments, and to the discretion historically exercised by public actors such as criminal prosecutors and juries when these actors were charged with racial discrimination. Third, the Court deferred to private choices and free markets to produce the optimal allocation of resources. Fourth, the Court supported traditional indicators of merit when these were challenged as racially biased.

Critical race theorists have painstakingly attempted to show how these jurisprudential developments, separately and together, block the possibility of political, economic, and social redistributions that would disrupt systemic racism. Some critiques have focused on unpacking the history and rhetorical structure of the Court's contemporary race jurisprudence to show how it redirects but does not challenge racism (Haney Lopez, 2007). Other scholars have mounted sustained attacks on particular doctrinal developments. For example, Devon Carbado and Cheryl Harris argue that by accepting the principle that the government can legitimately employ race when it is enforcing immigration laws, the Supreme Court has sanctioned racial profiling against Latinos, facilitated the merger of criminal law and immigration law with an expansion of police and prosecutorial power, and weakened constitutional protections against search and seizure in ordinary policing (Carbado and Harris, 2011).

A second theme of critical race theory is the attempt to articulate more expansive theories of race and racism than the Court's focus on conscious, intentional prejudice. Some critical race theorists have turned to economics to show how structural incentives in sites such as the workplace perpetuate racial stereotyping and racial cartels (Carbado and Gulati, 2000, 2003, 2004; Roithmayr, 2010). Others draw on sociology, history, and/or geography to theorize institutional or structural racism (Haney Lopez, 2000; powell, 2008). A number of critical race theorists have drawn on cognitive psychology and the theory of implicit bias to develop a theory of unconscious racism (Krieger, 1995; Robinson, 2008; Kang, 2010). This work builds on an early influential article by Charles Lawrence III, who attacked the Supreme Court's use of conscious intent to discriminate as the touchstone for Fourteenth Amendment equal protection clause jurisprudence (Lawrence, 1987).

A third theme within critical race theory is a move beyond the traditional black/white paradigm in the study of race relations. Much traditional US civil rights jurisprudence, and much early critical race theory, focused on caste racism against African Americans. A number of other critical race theorists, particularly those associated with the Latina/o Critical Theory (LatCrit) movement, have criticized this focus (R. Williams, 1991; Perea, 1997), and explored the racialization of other nonwhite groups in the United States, including Latinos, Asian Americans, American Indians, and mixed-race people (e.g., Chin et al., 1996; Berger, 2009; Hernandez, 1998, 2007). These scholars identify nativist racism as a phenomenon distinct from, although related to, caste racism and explore the political and social triangulation of racial groups defined as neither black nor white (Chang and Aoki, 1998; Chang and Gotanda, 2006–07). They have sought to recover and examine aspects of American race history such as the Chicano struggle for civil rights, Asian exclusion, and the colonization of Puerto Rico that have been neglected because they do not fit the traditional emphasis on African American civil rights (Gomez, 2007; Haney Lopez, 2003; Chin, 1998; Roman, 1997). Finally, this strand of critical race theory explores the convergences and divergences between race law, immigration and naturalization law, and federal Indian law (Villazor, 2008, 2010; Johnson, 2008, 2010).

A fourth theme within critical race theory has been an effort to understand how racism interlocks with other forms of oppression, including gender, class, and sexuality. From the beginning, many critical race theorists regarded themselves as feminists, and several addressed the failure of mainstream feminism to respond to the interests and perspectives of women of color (Crenshaw, 1989a; A. Harris, 1990). Later writers in this tradition sometimes refer to themselves as 'critical race feminists' (Wing, 2003), and have produced a body of work that criticizes legal institutions and legal doctrine from the perspective of women of color. The work in this tradition has come to treat race as only one axis of a multidimensional system of status oppression (Hutchinson, 1997), and, drawing on an early article by Crenshaw, much of it goes under the label of 'intersectionality' (see Crenshaw, 1989a). The LatCrit offshoot of critical race theory has devoted itself explicitly to intersectionality, exploring the interplays of race, ethnicity, religion, national origin, class, and sexuality (Valdes, 1998). More recently, critical race scholarship has explored the relationship between race and class (Jones, 2009).

Each of these thematic strands within critical race theory has engaged with the effort to work out the implications for legal theory of understanding race as a social construction rather than a natural fact. In this broader project, some critical race scholars have imported the work of sociologists Michael Omi and Howard Winant on 'racial formation' into the legal academy, studying the influence of state law on the racialization of whites and Mexicans (Gomez, 2007; Haney Lopez, 1996, 1998). Others have traced the differing meanings of *race* within judicial discourse and within social and political discourse to show how policy and legal conflicts often involve an unacknowledged manipulation of the term (Gotanda, 1991; Hernandez, 1998).

Future Directions for Critical Race Theory

One recent development within critical race theory has been an interest in the flip side of minority oppression: white privilege. One aspect of this development is an interest in exploring white identity, facilitated by a growing literature on critical white studies (Delgado and Stefancic, 1997; Flagg, 1998) and an interest in how racial discrimination affects whites (Rich, 2010). Additionally, there is growing interest in taking racial privilege rather than discrimination as the

object of study and critique (Wildman, 2005, 1996). Here, the argument is that the traditional focus on racism's victims leaves unexamined the everyday ways in which those who are not victimizers nevertheless benefit from racial hierarchies. This development is in keeping with the turn away from intentional discrimination as the touchstone for racism.

A second recent development within critical race theory is an expansion into private law. Some participants in an emerging critical tax studies movement have imported the themes and concerns of critical race theory into their work (Moran and Whitford, 1996; Brown, 1997). A few scholars of corporate law have examined corporate law doctrine and racial diversity issues within corporations from a critical race theory perspective (Wade, 2002; Carbado and Gulati, 2004). Others have incorporated critical race theory's concerns into examinations of contract, tort, and property law (Houh, 2005; Chamallas and Wriggins, 2010; Brophy et al., 2011).

A third development within critical race theory is a movement beyond the borders of the United States. One example of this move is a growing literature in critical comparative studies of race and law (Oppenheimer et al., 2012; Hernandez, 2003; Wing, 2001). Another example is the incorporation of themes from critical race theory into the international law context (Richardson, 2008; Gordon, 1997) and into discussions of international human rights, foreign policy, and international trade relations (Hernandez-Truyol, 2008; Gordon, 2009; Gordon and Sylvester, 2004).

A final recent development is the migration of critical race theory into other fields of legal scholarship and other disciplines. Critical race theory explores a subject matter of interest to sociologists, political scientists, historians, and anthropologists. Laura Gomez has noted the overlap in particular between critical race theorists and law and society scholars, advocating more collaboration (Gomez, 2004). Other scholars have argued for greater collaboration between critical race theorists and empirical researchers generally, citing the benefits to both types of scholarship (Parks, 2008; see Twine and Warren, 2000). As previously noted, a fruitful emerging collaboration between critical race theory and cognitive psychology concerns the concept of implicit bias (Kang, 2010), although others lament that "a critical race psychology is not yet born" (Adams and Salter, 2011). Critical race theorists and economists have worked together (Carbado and Gulati, 2000, 2003, 2004; see also Ayres, 2007). Finally, ethnic studies, cultural studies, postcolonial studies, and American studies have concerns, subject matter, and methods closely allied with those of critical race theory, and scholars in these fields freely borrow from one another's work.

Critical race theory has also moved further afield, where it is sometimes referred to as critical race studies. In particular, it has taken off in the discipline of education (Ladson-Billings and Tate, 1995; Ladson-Billings, 2011). A handful of philosophers exploring questions of racial equality have also drawn on critical race theory in their work (e.g., Pateman and Mills, 2007).

Finally, at least one law school has established a critical race studies certificate program for its students with a program that seeks, among other things, to promote a more comprehensive and comparative approach to the study of race and law (C. Harris, 2002). This development may be a harbinger of a shift of critical race theory from the margins to the mainstream of research and teaching.

Critical Rationalism

Abstract

Critical rationalism is a philosophy of rational thought and action founded by Karl Popper. It arose out of Popper's idea that falsifiability is the characteristic of empirical science. According to critical rationalism, there is no certain knowledge. All human thoughts and actions are fallible. Yet rationality and knowledge are possible. Rationality is openness to criticism, that is, the readiness to listen to critical argument and evidence. Critical rationalism has been criticized as being a form of skepticism and incompatible with the history of science.

Critical rationalism (CR) is a philosophy of rational thought and action founded by Karl Popper. By rationalism, Popper meant the attitude to solve problems by an appeal to reason, that is, to clear thought, experience, and argument. Rationalism in this wide sense covers intellectualism (rationalism in the narrow sense) as well as empiricism. In the history of philosophy, the idea of rationalism usually implied that we can achieve certain knowledge and that we should accept only what has been proven. CR, however, denies that certain knowledge is possible. All hypotheses and theories – moreover, all human attempts of solving problems – are uncertain and fallible. Therefore, we should always be prepared to correct our views. According to CR, rationality is the readiness to listen to critical argument and to learn from experience. CR arose out of Popper's (1934) methodology of science, and has been developed further by some of Popper's successors.

The Methodology of Falsificationism

In 1934, Popper published his classical text *Logik der Forschung*, which was translated into English in 1959 as *The Logic of Scientific Discovery* (hereafter, LScD). In this book, Popper posed the *problem of demarcation*. What is the characteristic of empirical science? How can science be demarcated from metaphysics and pseudoscience, on the one hand, and logic and mathematics, on the other hand? Popper did not propose as a criterion of demarcation the verification or proof of empirical theories. Theories are systems of universal statements, and such statements cannot be verified by observation. For example, no matter how many white swans we have observed, this does not prove that all swans are white. With reference to Hume, Popper rejected as invalid all kinds of inductive inference. Instead he proposed as a suitable criterion of demarcation the *falsifiability* of empirical theories. The hypotheses and theories of science must be refutable by experience. For instance, 'All swans are white' is falsifiable, since it can be refuted by the observation of a black swan. Similarly, the universal statements of physics can be refuted by contradicting experimental results. The observational statements that serve to falsify a theory must themselves be intersubjectively testable (e.g., by repeating the respective experiment).

For scientific research, Popper advocated the *hypothetico-deductive method*. Theories are posed without prior justification, and then critically tested. From a theory T, with the help of some background knowledge A (assumptions regarded as unproblematic in the given situation, e.g., auxiliary hypotheses and singular statements), a test prediction P is deduced. P is compared with the results of observation. If P is accepted as true, T is regarded as *corroborated*, provided the test was a serious attempt to falsify T. If P is rejected, T is considered as falsified.

Theories should be *severely* tested. They should, in every conceivable way, be exposed to falsification. However, theories can always be saved from refutation by introducing ad hoc hypotheses. Any hypothesis or theory can be immunized against falsification. In order to prevent this, Popper formulated a set of methodological rules. These rules propose how to proceed in specific research situations, and together define the critical method of science.

It is a major point of Popper's methodology that corroboration is not mere correspondence between theory and observation. It is the result of a failed attempt to falsify a theory. The degree of corroboration increases with the number and kind of tests the theory has passed. Once a theory has passed some tests, additional tests of the same kind raise the degree of corroboration very little. The theory may, however, gain additional corroboration by application in new fields.

It is not possible to prove with certainty that a statement is true or false. This holds for statements of any kind, including observation statements. Human cognition is fallible. Certain knowledge is impossible. Popper noted that fallibilism was stated more than 2000 years ago by Xenophanes. However, the characteristic of Popper's view is not fallibilism by itself but the combination of fallibilism with rationalism. Unlike skeptics and relativists, who also embrace fallibilism, Popper insisted that rationality and knowledge are possible. In his LScD, he wanted to point out what it is that constitutes rationality in empirical science. The two central elements of falsificationism are fallibilism plus the assumption that proceeding in accordance with the rules of the critical method is conducive to scientific progress.

LScD contributed to the debates of the Vienna Circle, a group of philosophers and scientists around Moritz Schlick. Members of the Vienna Circle had proposed to consider as meaningful only statements that could be verified by observation. On this view, metaphysical statements turn out to be meaningless. Popper rejected this view, which would also render the laws of nature as meaningless since they cannot be verified either. Popper loosened the standard of scientific rationality by replacing verifiability with falsifiability.

Furthermore, he insisted that what is unfalsifiable is not necessarily meaningless. He even granted that metaphysical ideas may be fruitful. Yet he thought it necessary to demarcate science from metaphysics. He believed that rational discussion is possible in science but not in metaphysics.

From Falsificationism to Critical Rationalism

Roughly 10 years later, Popper was concerned with problems of social and political philosophy. In his *The Open Society and Its Enemies*, he criticized the political theories, and their philosophical roots, of Plato, Hegel, and Marx. He also defended what he called the *open society*, in which individuals are personally responsible for their decisions, and in which it is allowed to put forward criticism, including criticism of the government. Popper considered as the basic principle of democracy that institutions are organized in such a way that people can replace governments without resorting to violence. In politics, as in science, Popper suggested replacing questions of justification with questions of criticism. Instead of asking the traditional question 'Who should rule?' we should ask how to organize institutions so that we can get rid of bad rulers.

Popper also addressed problems of social engineering. He considered as most dangerous, and vehemently rejected, what he called utopian engineering, which means the reconstruction of a society as a whole in order to realize an ideal state. We do not possess the knowledge necessary to achieve such an ambitious aim. Social action has unintended consequences. Utopian engineering will probably destroy the existing institutions and may lead to a dictatorship. Popper regarded as rationally justified only *piecemeal engineering*, which is small scale and continuously corrected in the light of experience.

In this context, Popper was confronted with an epistemological difficulty (Wettersten, 1992, Chapter 9). He had stated in LScD what rationality is in empirical science. But how could he argue for or against assumptions that are not empirical theories (e.g., assumptions of social philosophy or ethics)? And how can methodology itself claim rationality if its statements are not falsifiable, as are the statements of science?

Popper had loosened the standard of scientific rationality from proof to falsifiability, but he lacked a criterion of rationality applicable in other areas than science. Falsifiability could not serve that purpose. It would be too high a standard of rationality in metaphysics, ethics, or social philosophy. In his *The Open Society and Its Enemies*, Popper defines rationality as an attitude of *being open to criticism*. Rationality is the readiness to listen to critical argument and to learn from experience. It is "an attitude of admitting that I may be wrong and you may be right, and by an effort, we may get nearer to the truth" (Popper, 1945, vol. 2, p. 213). The idea of being open to criticism is, of course, somewhat vague. It has to be specified for the respective domain in which it is applied. It is a central concern of the CR program to specify what it means (e.g., in science, politics, or law) to proceed in accordance with the critical method.

Popper conceded that the rational attitude cannot itself be proven by argument, since only those who have adopted it will be impressed by argument. He concluded that rationality must be based on a decision, and on a faith in reason that must itself be described as irrational.

In later works, Popper (1963, Chapter 8) explained how philosophical or metaphysical theories can be rationally discussed even though they are not falsifiable. One can raise the question whether, and to what degree, a theory is able to solve the problems it is said to solve. Such an analysis may lead to the conclusion that a metaphysical theory does not solve any problem at all, or that one metaphysical theory is able to solve a problem better or solve more problems than another, and should therefore be preferred. Popper demonstrates, for example, how determinism and idealism can be assessed, and he rejected these views. Similarly, he argues against instrumentalism and for realism (Popper, 1963, Chapter 3).

So far, two components of CR have been pointed out. The first is *fallibilism*. The second is the *plea for rationality*, where rationality is conceived of as the critical attitude. Alternatively, one could state the second component by saying that the critical method is the best way of addressing problems of knowledge or action. According to Hans Albert (1999, Chapter 1), there is a third component of CR, namely, *realism*. Realism is conceived of as the views that there is an objective world existing independently of mind and language, and that we can achieve knowledge about this world. It is important to note here that, for CR, knowledge does not mean certain belief but corroborated yet fallible conjecture. For example, we know that the earth is round and not flat in the sense that the first hypothesis is highly corroborated while the second has been falsified.

In connection with realism, most critical rationalists adopt the *correspondence theory of truth*, the idea of truth as correspondence to the facts. That is, a statement is defined as true if and only if what it states is really the case. Otherwise it is false. This definition says only how truth and falsity are conceived of, and does not answer the methodological question of how truths and falsehoods are to be detected.

Fallibilism represents the (moderately) skeptical aspect of CR, and realism represents its optimistic aspect. Popper emphasized that there is no certainty, yet he declared truth (or truthlikeness) as the aim of science. CR vehemently rejects any kind of dogmatism or fundamentalism, and also rejects radical skepticism, relativism, and antirealism (including the various forms of constructivism).

CR is Popper's main contribution. But others have also contributed to CR as it exists today. Among them are Joseph Agassi, Hans Albert, Gunnar Andersson, William W. Bartley, David Miller, Alan Musgrave, and John Watkins. Imre Lakatos' (1970) methodology of scientific research programs is not regarded as a version of CR but as an alternative approach since it assumes that the hard core of a research program is immune to criticism, an assumption that is not in accordance with CR.

It should be noted that CR is not the same as Popper's philosophy in general. Popper wrote on many different subjects and developed many views that are independent of the basic assumptions of CR. Some of these views (e.g., his 'logic of situation' or his theory of the three worlds) are not shared by many critical rationalists.

Criticizing Critical Rationalism

Popper's *Open Society* became widely known and made its author famous. Some critics found his interpretation and

devastating critique of Plato and Hegel unconvincing. But his plea for the open society and for the critical attitude was widely accepted.

When Popper had developed CR, he had not yet reconsidered and improved his earlier methodology of falsification. This methodology was embraced by many scientists, but rather criticized by philosophers. The critics argued that scientific theories were not conclusively falsifiable since one could always decide to give up auxiliary hypotheses instead of the central laws of a theory. In the history of science, major theories were protected from falsification. Theories were retained, the empirical results that contradicted them were put into question, and often it turned out later that these results had been based on false assumptions (Chalmers, 1999, pp. 87–91). And, most importantly, such developments happened in periods in which great progress was achieved. CR was therefore said to be incompatible with the way famous scientists like Galilei and Newton proceeded. Popper's main critics who argued from the history of science were Thomas Kuhn (1962) and Paul Feyerabend (1975).

Some critical rationalists, such as Andersson (1994) and Musgrave (1999, Chapter 11), also studied the respective historical facts but came to another conclusion: Popper's methodology is quite in agreement with the history of science, and the criticism by Kuhn and Feyerabend is unfounded. Admittedly, scientists sometimes retain theories and reject results of observation, but this is quite in agreement with CR, for CR declares observations and auxiliary hypotheses as fallible.

Critics responded by asking what CR actually contributes if it allows rejecting either theories or observational results. Is such a methodology really different from Feyerabend's 'Anything goes'? Now CR commits to the hypothetico-deductive method. From a theory T and some background knowledge A (hereafter, T & A), a test statement P is deduced. P is compared with the results of observation. If P is rejected, some statement that belongs to T & A has to be given up, for, if non-P is true, T & A are necessarily false. The conjunction of T & A with non-P is inconsistent. Something has to be changed in order to regain consistency.

This is clearly different from 'Anything goes.' But it is not different from the view most philosophers of science hold. Does CR offer anything more specific than the hypothetico-deductive method?

Improving the Methodology of Critical Rationalism

The answer to the last question lies in the *methodological rules* of CR. But there is no single answer. One has to distinguish between Popper's view in LScD, his later view, and the views of other critical rationalists.

The hypothetico-deductive method leaves many decisions to the researcher. For example, any theory has infinitely many logical consequences. We may therefore ask, first, whether CR can give some advice regarding which consequence should be selected for testing. Second, if the result of the test is non-P, which part of the system T & A should be declared as false? This is known as Duhem's problem. Third, once it has been decided that T is to be regarded as falsified, is this judgment final or may it be revised?

As to the first question, Popper specifies that P not only should be derivable from T & A but also must not be derivable from other theories than T (Popper, 1959, p. 33). Even better, P should contradict other theories, especially those competing with T. Thus, P should be an implication from T that is extremely unlikely in the light of other views we have held true. We may call this the *rule of critical testing*, because the test is planned in such a way that the empirical result either falsifies T or teaches us that some well-corroborated theory T′ seems to contain a mistake. In each case, the result fosters the growth of knowledge.

Concerning the second question, Popper allows the introduction of new auxiliary hypotheses in order to retain the theory that is contradicted by observations. However, he sets some restrictions. No ad hoc hypotheses must be introduced. Popper also decides that new auxiliary hypotheses must not decrease the empirical content (or degree of falsifiability) of T & A, but rather should increase it (Popper, 1959, pp. 82–83). And he rejects the strategy of explaining away threatening observations by appeal to some unknown disturbances, or to the incompetence of researchers.

The last point seems uncontroversial. Saving theories from refutation with the help of untestable speculations does not further the growth of knowledge. However, the rule never to decrease the content of T & A appears to be too strong, and often not applicable. If non-P contradicts T & A, and T is retained, some assumption within A must be declared as false. The new system T & A′ must be consistent with non-P, and is therefore inconsistent with T & A. This, however, renders it very difficult to compare the two systems with respect to empirical content. (Comparing the content of systems is easy if they are consistent with each other and one of them implies the other one logically.) Furthermore, it is very restrictive to require that the empirical content must never decrease. Empirical content is an important aim in theory building, but there are also other aims (e.g., simplicity) and, primarily, correspondence to the empirical facts. In the course of scientific research, it is not always possible to achieve an increase in all dimensions of progress.

With respect to the third question, Popper wrote (1959, p. 268), "In general we regard an inter-subjectively testable falsification as final (provided it is well tested)." It is not easy to interpret what Popper wanted to say here. It seems that this statement is not in accordance with other parts of LScD or with the spirit of fallibilism. How can a falsification, that is, a decision to declare a theory as false, be final or conclusive if auxiliary hypotheses as well as observation statements are fallible? In his postscript to LScD, Popper made clear "that it is never possible to prove conclusively that an empirical theory is false" (Popper, 1983, p. xxii). This is the view to which all critical rationalists have agreed. Since observations and auxiliary hypotheses may be erroneous, the judgment that a theory is false is itself fallible and may be revised.

As to Duhem's problem, the answer is systematic trial and error. If non-P obtains, it is up to the researchers to speculate where the false assumption(s) is located. They have to decide to modify either T or A and to replace the respective assumption by a new one. The result, T′ & A, or T & A′, is then again tested in order to find out whether T′ & A, or perhaps T & A′, is empirically more successful than T & A. This procedure is continued

until the system is corroborated, or the whole theory T is given up in favor of a new approach. However, CR does not specify when exactly a theory should be given up. There is no criterion of final falsification. But CR assumes that science is quite successful in deciding when it is reasonable to give up a certain theory and replace it with a better one.

So far, some methodological rules of CR have been discussed. There are many further rules in Popper's works (Jarvie, 2001). Most of them can be interpreted as *heuristic principles*. They recommend thinking in a certain direction in order to solve the problem at issue, but they do not exactly prescribe what to do. For example, according to the rule of critical testing, one should try to derive from T a test statement that does not follow from other theories. This excludes many logical consequences from T but still leaves the selection of the best test statement to the imagination of the researchers. Hans Albert (1999, Chapter 2) therefore conceived of methodology as a kind of heuristics.

As to the logical status of methodological rules, Popper realized that they are not analytical statements and not empirical statements (descriptions of what scientists do). Popper (1959, p. 53) therefore declared them as conventions that define the game of science. Albert (1999, Chapter 2) instead proposed to regard methodology as a special kind of technology. The statements of methodology say that certain procedures are conducive to the aim(s) of science. Suppose the aim of science is the development of true theories of high explanatory power. The idea of critical testing may then be formulated as follows: 'Critical testing contributes to achieving true, powerful theories' (Gadenne, 2006).

The methodological rules cited here are considered as relevant for natural science as well as for the social and cultural sciences. Of course, the various disciplines use different research techniques. They are concerned with different objects, and they therefore need different methods of observation, measurement, and statistical analysis. However, the fundamental methodology is the same in all empirical sciences. The hypothetico-deductive method, and the specific rules associated with that method, can be used effectively in physics and biology as well as in the apprehension of the meaning of actions and the meaning of texts (Mantzavinos, 2005).

Thus, CR has more to offer than mere deductive thinking. Critical rationalists differ, however, in regard to the significance of methodological rules. Some think that the hypothetico-deductive method is the main answer to the questions of methodology, and the additional rules are of secondary importance. Others believe that Popper made an important step when he pointed out that deductive logic is not sufficient for methodology. There are many pragmatic aspects of research to which deductive logic has nothing to say but that are central for the rationality of science. They do not concern the logical properties of statements but the way scientists proceed when they test, discuss, and evaluate these statements.

Popper also introduced the *social* dimension into the methodology of science. He considered science as a social activity and was convinced that rationality requires cooperation. Robinson Crusoe could not do science, Popper said. One individual is not able to both develop and test a theory effectively. Jarvie (2001) pointed out that these thoughts laid the foundation for a theory of the institutions of science. It depends on social rules and on the institutions of science to which degree scientists can follow the methodological rules that CR declares to be conducive to progress. These institutions can foster or hinder rationality. For example, in some domains there is a tendency to appreciate more, and prefer for publication, data that confirm a hypothesis to data that refute a hypothesis. However, if 'mere criticism' (instead of 'positive results') is considered by a community as not worth being published, this hinders learning from experience. In this context, CR encourages the study of the institutions of science (Wettersten, 2006; Albert, 2010).

When Popper developed falsificationism, his main concern was the demarcation of science. Is this still a major point of CR? Popper had granted that metaphysical (or philosophical) ideas may be fruitful for science. Some falsifiable scientific theories arose out of metaphysical ideas. Atomism is an example. Later, Popper came to the conclusion that metaphysical theories could even be rationally assessed. Agassi (1975) went one step further. On his view, most scientific theories were attempts to give answers to metaphysical questions (e.g., 'From what is everything made?'). Metaphysics is also a source of ideas for science. It can guide scientific research by giving standards for desirable theories and explanations. Metaphysical theories can then become research programs. From the critical perspective, it is advantageous if two or more research programs compete with one another. Agassi expounded how Faraday used his metaphysical field theory as a framework within which he developed physical field theories. (Agassi's view influenced Lakatos's methodology of research programs.)

In psychology, the metaphysical idea that cognition is information processing has become important as a framework for the construction of many theories. A rival program is based on the (metaphysical) view that all mental processes are nothing over and beyond brain processes, and should correspondingly be studied by neuropsychology. The metaphysical assumption that humans always try to maximize utility has been a framework for economic theories. From the viewpoint of CR, it is unfortunate that in the latter case, there is no competing program of equal influence. If metaphysical views become too dominant in science, this may impede the growth of knowledge.

This gives rise to reconsidering the problem of demarcation. When Popper developed CR, he continued to regard the demarcation of science as of the utmost importance. But is this still justified? In CR, the boundary of science is no longer the boundary of rationality. So why still demarcate science from metaphysics? According to Wettersten (1992), this demarcation is a residue of positivistic thought. Albert (1985, Chapter 5) argued against drawing boundaries between disciplines. Such bounds often foster the immunization of theories against criticism from other perspectives.

One demarcation that remains significant is the idea of rationality as openness to criticism. CR rejects all kinds of dogmatism and fundamentalism, which refuse to take note of any unwanted evidence or argument, and consequently rejects such metaphysical approaches that are essentially dogmatic. But here the boundary is not between science and metaphysics but between the critical attitude and dogmatism. Dogmatism can sometimes be found even in science, and metaphysical traditions may place great importance on assessing their views critically.

Today many philosophers of science hold that philosophy should only try to understand, describe, or reconstruct what science does, but never evaluate or criticize it. Some even consider it as presumptuous on the philosophers' part to tell scientists what to do or not to do. By contrast, CR deems its task a critical one. Philosophy should critically analyze the developments in science, point out problems from the metascientific perspective, and also be open to criticism from science. In accordance with this view, Popper (1982) criticized the Copenhagen interpretation of quantum mechanics by Niels Bohr. Albert criticized strategies of immunization in economics, of making theories and models irrefutable, for instance, by using unspecified ceteris paribus clauses (Albert et al., 2012).

Reason and Nonjustificationism

Most philosophers closely associate rationalism with the idea of justification, of giving reasons for what one believes. CR, however, rejects justificationism because the search for proof leads to unsolvable problems. Albert (1985) demonstrated this by considering the principle that one should accept a statement if and only if one can give a sufficient reason for it. A reason for a statement A is regarded as sufficient if it makes A absolutely certain, or guarantees that A is true. This, however, leads into a fatal situation that Albert called the 'Münchhausen trilemma.' One has three possibilities, none of which solves the problem. In order to prove A, one has to accept some other assumption B as a reason for A, which has in turn to be proven, so that one gets into an infinite regress. Or one has to argue in a circular way. Or one has to stop the process of justification by adopting some assumption dogmatically. In each case, one has not succeeded in sufficiently justifying A. CR offers as a solution to give up the principle of sufficient reason and replace it with the principle of criticism.

But is criticism an end in itself? Must we abandon any justification by giving reasons once we have accepted fallibilism? Or can we conceive of an idea of justification that does not involve certainty? Isn't it, for instance, justified to believe that the earth is round and not flat, though this belief is fallible? Does CR hold that there are no sufficient or certain reasons, or that there are no reasons, sufficient or not, for anything at all? With respect to this problem, there are two groups of critical rationalists who maintain different views.

Musgrave (1999) interprets CR as saying that it is not possible to justify a hypothesis (or theory), but it is possible to justify belief in, or acceptance of, a hypothesis. A universal statement cannot be inferred, by deduction or induction, from observation statements. In this sense, it cannot be justified. Yet it is reasonable to believe in a hypothesis or theory, or to adopt it as true, if it has withstood serious criticism. If there are several competing hypotheses, it is reasonable to adopt the best-corroborated one. More exactly, *it is reasonable to (believe) adopt as true A (at time t) if and only if A is the hypothesis that has (at time t) best withstood serious criticism*. According to Musgrave (1999, p. 324), this is the central principle of CR.

Popper's view is slightly different. He regarded as incautious the claim that a theory is true. According to Popper, truth is a regulative idea, a standard by which we usually fall short. Even the best scientific theories are oversimplifications, and therefore we never have reason to believe in their complete truth. But we may have reason to believe that one theory is a better *approximation of the truth* than another. More exactly, Popper (1972, p. 82) said we could have reasons for the following claim: "This theory seems at present, in the light of a thorough critical discussion, and of severe and ingenious testing, by far the *best* (the strongest, the best tested); and so it seems the one nearest to truth among the competing theories." Such a claim is fallible but may be justified by the current state of the discussion.

Popper also gave a formal definition of *truthlikeness* or *verisimilitude* (1963, Chapter 10) that, however, turned out to be untenable. Others have tried to improve Popper's attempt, but all proposals raise difficult new problems. Popper (1983, p. xxxvi) finally came to the conclusion that a formal definition is not necessary, and that the idea of truthlikeness could be made sufficiently clear with the help of examples. For instance, Kepler's theory that the planets move in (not very elongated) ellipses with the sun in their common focus is a better approximation to truth than Copernicus' view according to which the planets move in circular orbits. It is controversially discussed whether methodology needs the idea of truthlikeness, and whether a formal definition is necessary.

Thus, with respect to justification, Popper's view is similar to Musgrave's, but Popper preferred to talk of approximation to the truth (or verisimilitude) instead of truth. He (1972, p. 103) also said that the degree of corroboration of a theory could be taken as an indication of its verisimilitude.

Does this mean that CR needs and (implicitly) accepts a form of *induction*? This depends on how induction is conceived of. There are at least three kinds of induction that CR can dispense with. First, as Hume and Popper pointed out, the truth of observation statements never guarantees the truth of a universal theory. Second, attempts to define the confirmation of a theory as an inductive probability have not yet been successful. Third, the major theories of science have not been discovered by applying formal inductive rules. (Otherwise, anybody could have developed these theories.) However, if any principle for the acceptance or preference of evidence-transcending statements is called inductive, then Musgrave's (and, as it seems, Popper's) CR includes an inductive principle.

Now there is another group of critical rationalists who abandon not only the aim of certainty but any kind of justification. Bartley (1984, p. 104) criticizes Popper's view for being not entirely consistent. Popper proposes that rationality is openness to criticism, yet his view is not completely nonjustificational since he thinks that the critical attitude had to be based on a faith in reason. Bartley calls such a view *fideistic*. As an alternative, he offers his *pancritical rationalism*, which does not even seek to justify itself. Pancritical rationalism keeps everything open to criticism, including itself. The traditional demand 'How do you know?' is answered by 'I do not know.' The request for justification no longer arises. Instead, it is asked, "How can our beliefs, conjectures, policies, traditions, and the like be exposed to maximum criticism?"

Miller (1994) holds a similar view. There is reason and rationality, but there are no good reasons, no sufficient or

partly sufficient reasons for accepting or rejecting any assumption. The aim of science is to retain as many true statements and to single out as many false statements as possible. The appropriate strategy is Popper's method of conjectures and refutations. Hypotheses are admitted to science if they are falsifiable by experience. If a hypothesis fails the tests to which it is submitted, it is removed from science. If it passes the tests, it is retained. But, most importantly, the passing of tests makes no difference to the status of a hypothesis. That is, the hypothesis does not become more plausible or more probable. Neither does it gain any kind of support or credibility. It remains forever as uncertain as it was when it was invented and yet untested. Neither theories nor observation statements can be justified. If a theory is classified as false, this is done without the claim that one could justify the respective observation statements. The latter are themselves fallible and open to dispute.

Miller (2006, Chapter 7) conceded that this is a form of skepticism. He emphasizes, however, that it is not relativism. Relativism claims that there is no absolute truth, though there are many relative truths. Miller holds that there is absolute truth to be had, but insists that we can achieve it only by making lucky guesses, and can never justify these guesses.

The view that theories can never gain any empirical support is, of course, different from what most scientists and philosophers think. Some critics deem CR a modern kind of irrationalism. The group of critical rationalists represented by Bartley and Miller, however, think that CR presented an ingenious solution of the problem of induction, which has not yet been understood by the majority of scientists and philosophers, because they have not yet escaped justificationist thought. According to Miller (2006, p. 112), this is a 'scandal of philosophy.'

Critical Realism in Geography

Andrew Sayer, Lancaster University, Lancaster, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The nature of critical realist philosophy and its relevance to geography are outlined, including its fallibilism and distinctive way of understanding causation, which is especially appropriate for the study of the irregular behaviors that typically confront geographers. It also acknowledges that the intrinsically meaningful character of social phenomena requires interpretive understanding of meaning in society. Further, it defends a critical stance toward the ideas and practices studied by social researchers. Some implications for methodology are sketched, and illustrations are given of research informed by critical realism in geography. Finally, critical responses to critical realism are summarized.

Introduction

Critical realism is a philosophy of and for the social sciences that has had an impact on methodology in geography since the 1980s, although there have always been realist elements in geographical thought. With the rise of critical realism, these and further elements were developed and promoted self-consciously, while non or antirealist elements were attacked. Since its high point in the 1980s and 1990s various nonrealist developments and other kinds of realism have come to the fore.

A Definition

Critical realism argues that the natural and social worlds we study exist largely independently of the researcher, and that there is necessity in the world which enables and constrains what can happen. Causation is to be understood in terms of the powers that objects possess rather than in terms of empirical regularities among events; if and when these 'causal powers' are activated, the results depend on contexts, and are unlikely to be regular. Since social phenomena such as actions and ideas are intrinsically meaningful, unlike the subject matter of the physical sciences, their meaning also has to be interpreted. The world can only be understood in terms of available discourses. While there are no privileged routes for discovering the truth about the world, and empirical tests are themselves fallible, it is often possible to distinguish better from worse accounts in terms of their adequacy for informing material practice.

Intellectual Context

Critical realist philosophy was developed by Roy Bhaskar out of his earlier work on the philosophy of natural science ('transcendental realism') (Bhaskar, 1978, 1989). The latter sought an alternative to both those positions which treat knowledge as straightforwardly based on observation and experience (empiricism) and for which truth is a simple matter of correspondence between statements and the objects to which they refer, and various relativist positions which treat the truth of theories as purely relative to discourses. Critical realism also steers a course between positions which regard social science as the same as natural science and those which treat it as entirely different.

Realism and Fallibilism

The most fundamental realist assumption is that much of the world can exist independently of an observer's knowledge of it. The plausibility of this assumption rests upon the fallibility of knowledge; the fact that knowledge claims sometimes prove to be mistaken and generate false expectations implies that the world is not a product of our thought but is whatever it is regardless of what we think about it. Realists reject the empiricist view that reality is whatever we can experience since this implies an improbable coincidence between the world and the limits of our sensory powers, and implies that either knowledge is already complete, or that new knowledge creates new objects. Critical realists accept that our observations and knowledge are always formed through available discourses or are 'theory laden,' so that we can never escape from our conceptual frameworks to see how they compare with the world they seek to represent. However, that observation is theory laden does not necessarily mean that it is entirely determined by theories and so it can still be possible to compare the adequacy of different theories from within discourses and find observations which contradict expectations. This offers a way of avoiding the relativist view that truth is merely relative to theoretical systems. It also implies that science can make progress in explaining the world even though absolute truth is not an intelligible goal.

Critical realism therefore does not involve claims to have a privileged access to the truth about the world, a uniquely 'realistic' view, for the very independence of the world from our knowledge of it renders such claims problematic. It must necessarily view all knowledge as in principle fallible, although this does not mean, of course, that it is all false or all equally true or untrue.

Key Arguments and Their Influence on Geography

Critical realism became influential in geography partly for the above reasons, for geographers, like other scientists, were

seeking a way of understanding science that avoided the unappealing alternatives of empiricism and relativism. However, a further important factor was probably its view of causation and systems. Some of the first discussions of critical realism in geography emphasized this issue and its implications for the nature of theorizing in geography (Sayer, 1982, 1985).

The scientific revolution in geography, exemplified by *location theory* and *spatial analysis*, had largely assumed that causation was a matter of empirical regularities or 'constant conjunctions' among causes and effects. It was expected that understanding of the regularities in spatial organization of phenomena would grow to the point where it would be possible to formulate laws about them. This regularity-based view of causation had dominated the philosophy of science despite the fact that, particularly in social sciences like human geography, there appear to be few enduring precise empirical regularities, so that the search for laws of social and spatial behavior has been singularly unsuccessful. For realists this is unsurprising. For them, causation is a matter of what produces change, not a matter of empirical regularities in sequences of events. Objects have causal powers, that is, the power to act in certain ways. A seed has the power to germinate, a person the power to work. These objects have these powers in virtue of their structures, such as the biochemical constitution of the seed, or the anatomical and mental structures of a person. Whether these powers are ever activated depends on conditions whose presence is contingent, that is, neither necessary nor impossible, such as moisture and solar energy in the case of the seed or a need for food in the case of the person. Furthermore, the particular effects which follow when these causal powers are activated depends on conditions which again are contingent. The germination of the seed may be encouraged by fertilizer or halted by herbicides, the attempt of the person to work may be hampered by lack of tools or encouraged by their availability.

This alternative conception of causation has far-reaching implications. First, since it dissociates causation from empirical regularities, it enables understanding of how unique events, as much as repeated ones, can be caused. Second, it focuses on necessity and contingency rather than regularity or the search for empirical order. Third, in view of this, explanation does not require repeated observations: what makes something happen has nothing to do with the number of times it has or has not been observed to happen. It follows from this that the old debate in geography between idiographic and nomothetic approaches – the former a supposedly nonscientific study of the unique, the latter a supposedly scientific search for laws – was falsely based. Regardless of whether phenomena were unique or widely replicated, they could be explained in the same way.

The uniqueness of many geographical phenomena no longer posed a threat to geography's scientific status. Fourth, it became possible to see that the search for generalizations is distinct from explaining how causes work; generalizations, as the term suggests, attempt to tell us how common or extensive certain phenomena are, and this is different from explaining how they are produced. The greater part of standard literature on the philosophy and methodology of science had confused these two things, and many geographers had done so too. Fifth, the realist account offers a way of understanding how it is possible for the same cause to produce different effects and for different causes to produce the same effects, since the relationship between causal powers and empirical outcomes is not one of automatic regularity but is dependent on the conditions within which they are located.

An example of this can be given from a kind of economic geography which was popular at the same time critical realism became influential. The geography of industrial restructuring looked at changes in economic geography in terms of how competitive pressures upon firms to restructure produced responses (e.g., Massey and Meegan, 1982). In realist terms, competitive pressures on profit margins were considered as the main causal power of interest here, with their effects being mediated by a wide range of contextual circumstances, such as the particular cost structures of the firms under pressure, the scope for technological change, and the availability of various kinds of labor. Thus, in an industry such as clothing, which had little scope for further automation or speeding up work, and in which wages were a major element of costs, a common response was to seek out cheaper sources of labor, sometimes by relocating.

By contrast, in industries which were more technology intensive and had scope for further automation, a more common response was technological innovation. By such means, it was possible to explain how the same or similar causes could produce radically different results according to context, whereas approaches which rested upon the discovery of empirical regularities foundered. Similar research also illustrated how a single kind of outcome – job losses – could have completely different causes, for example, a drop in demand for the firm's products, or the introduction of automation during steady or rising demand, or reorganization of work routines to eliminate idle time and intensify work (see also Henry, 1992). For further discussion of these topics *see* Economic Restructuring: Geographic Aspects.

One of the most important and lasting influences of critical realism on geography has been on its empirical research designs (Sayer, 1992, 2010). Hitherto, the dominance of conceptions of explanation as tied to generalizations about empirical regularities had been used to privilege 'extensive' research designs which sought to uncover such regularities or patterns of covariation. Although these are, as the term indicates, useful for establishing how extensive certain phenomena are, they do not necessarily identify causes, as opposed to spurious correlations. The latter are likely to be thrown up by extensive research because it preselects groups of objects taxonomically, that is, on the basis of similarities (e.g., industries of a certain kind), rather than functional connection. By contrast, intensive research designs, including ethnographic case studies, focus on causal rather than taxonomic groups and follow up causal connections wherever they lead – often between heterogeneous objects, such as firms of different kinds. Intensive research is typically more exploratory, since the purpose is to discover the relevant causal groups. It is often time consuming to do this for large numbers of cases, and therefore it is not always a good basis for generalization. However, as we have seen, this lack of generalizability does not undermine the status of causal explanations of the

particular cases which are studied intensively. Consequently, having formerly been regarded as unscientific, intensive studies have now become more accepted in geographical research.

Critical realism acknowledges that the methodology of social science must diverge from that of the natural sciences because human, social phenomena are intrinsically meaningful. While the objects that, say, geologists study, are what they are regardless of any meaning people may give to them, objects such as socially segregated urban areas depend on the meanings actors give to them. To understand what these are, one has to know what their meaning is in society, whereas the nature of a rock does not depend on how its constituents understand one another, as they do not. Consequently, an important part of the methodology of human geography, no less than other social sciences, is interpretive understanding. For example, to understand the geography of the Middle East, we would have to understand what significance its land had for Jews and Arabs in terms of their identities.

Although this interpretive understanding has also been the focus of *humanistic geography*, critical realists make certain qualifications which the latter might not. The three most important are as follows. First, critical realists argue that although we have to interpret the understandings that actors have of their situations in order to make sense of how they act, their understanding is not necessarily a good one, indeed it may be systematically flawed. Moreover, these misunderstandings may have important effects which actors cannot explain. Thus a misogynist may believe that the proper spatial location for women is in the home, on the false grounds that they are incapable of coping with life in the public sphere; the falsity of this understanding makes a difference to what happens and therefore has to be acknowledged in scientific accounts. Further, different actors may give contradictory accounts of the same situation: where this is the case the researcher cannot sit on the fence and say both are correct. Actors' accounts of situations therefore face social scientists' accounts both as objects of study and rivals. It is therefore likely that researchers' accounts will be at least implicitly critical of actors' accounts – a conclusion which humanistic geographers are generally unwilling to accept. It is primarily for this reason that Bhaskar's philosophy of social science is called *critical* realism.

Second, among the intrinsically meaningful aspects of social phenomena are actors' reasons. Critical realists argue that reasons can be causes, since they can be responsible for producing change, by prompting actions. This, of course, implies that realists do not limit causation to physical processes. To deny that reasons are causes is to imply that the giving of reasons by actors is ineffectual and redundant, which of course makes it unclear why they are given. Third, an insistence on the necessity of interpretive understanding should not allow us to forget that social life is also material, embodied, and spatially situated, and that things happen *to* people, so that, for example, they can be dominated, sometimes regardless of their understanding of the situation.

The realist facility for explaining irregular processes was particularly attractive to a discipline such as geography, concerned as it is with spatial differentiation and uneven development, and hence unable to ignore – as, say, economics tries to do – the problems of applying equilibrium models or making generalizations which are supposed to hold across time and space. The systems which geography and other social sciences study are *open*, that is, their elements can themselves be undergoing internal qualitative change – actors aging and learning, for example – and the relations among the elements are not constant, with the result that any empirically regular behaviors are unlikely to be durable or widespread. Evolutionary change and disequilibrium rather than equilibrium are the norm.

Where previous attempts at scientific explanation in geography had tried to evade the prevalence of differentiation and irregularity, on the mistaken grounds that explanation required the discovery of regularity, human geography began to reembrace differentiation, nowhere more strikingly than in Doreen Massey's influential *Spatial Divisions of Labour* (Massey, 1984). This was closely followed by a burgeoning literature on locality studies, which typically focused on how economic restructuring worked out in different localities, and how those differences impacted back on the restructuring process (e.g., Cooke, 1986).

Critical Reception

Some geographers feared that such concerns heralded an abandonment of theory and generalization and a slide toward the empiricist documentation of facts (e.g., Harvey and Scott, 1989), indicating a resistance to the critical realist de-emphasis of generalization. These fears were not merely methodological but partly about a weakening attachment in economic geography to a particular kind of theory – Marxism – and also a tendency to treat critical realism as a source of substantive theory rather than as a philosophy, when it had no such pretensions. At the same time, some of the attempts to use critical realism in localities studies invited justified criticism by arbitrarily translating it into the study of general, supralocal causal processes interacting with local contingent conditions. However, critical realism did not license such an extraordinary alignment of scale and necessity: the supralocal is no more or less the realm of necessity than the local, nor is the local any more the realm of contingency than the supralocal.

Toward the end of the 1980s a newer generation of geographers became influenced by postmodernism (*see* Postmodernism in Geography). In some ways this continued the emphasis on differentiation – only phrased as 'difference' which had connotations of social differences of identity. One of the positive features of this literature was that it gave greater concern to the textual nature of accounts of the world (Sayer, 1989; Stones, 1996). Particularly in actor network theory, the world was seen as inherently messy, and skepticism toward grand universalizing accounts of the world grew. At the same time, some postmodernist writers rekindled relativist, antirealist tendencies (e.g., Barnes, 1996; Graham, 1990), although sometimes by mischaracterizing realism as claiming privileged access to the truth rather than as having a fallibilist view of knowledge.

In recent years interest has grown in 'assemblage theory' (Anderson et al., 2012; Saldanha, 2006). This derives from the

work of Gilles Deleuze, and, as Manuel DeLanda has argued, represents a different kind of realism (DeLanda, 2006). Where critical realism has tended to assume that the world is made up primarily of relatively durable structures of interlocking parts such as capitalist firms or other organizations, assemblage theory treats the world as a consisting in combinations of externally related elements that interact in various ways that depend on the manner of their combination, but which can also break away and form new assemblages. Thus the emphasis is on processes of formation and transformation or dissolution. This has obvious appeal for understanding 'messy' objects such as cities and regions. Like critical realists, assemblage theory acknowledges the possibility of 'emergent powers,' that is, powers that emerge from particular relationships between elements and which are irreducible to the powers of their constituents. However, for assemblage thinkers, applying theoretical concepts of familiar structures in empirical research to actual cases is suspect: it is liable to underestimate the open-endedness of processes of formation of assemblages from preexisting elements. Instead, the assemblage approach suggests a more cautious and bottom-up style of investigation into the formation of assemblages, rather than one which 'draws down' and applies familiar concepts such as 'neoliberalism' or 'globalization' to cases.

This is a new incarnation of an old concern in geography about theory and empirical research whose previous incarnations include the debate between idiographic and nomothetic approaches in the 1960s and 1970s, and between narrative and analysis in the 1980s and 1990s (Sayer, 2000). Each incarnation adds something different. Where critical realism emphasizes the centrality of conceptualization to theorizing, postmodern, and post-structuralist sensibilities push further the questioning of familiar categories, for example, challenging familiar dualisms such as nature/culture and problematizing the nature of boundaries between things so that they are seen as contingent outcomes rather than as givens. Perhaps too much emphasis on the messiness of the world may lead us to neglect the power of our best theories to help us see the wood for the trees, so that we render what may be recurrent structures as ad hoc assemblages. Whatever the case, realism's emphasis on ontology, on theorizing the basic composition of the world, evident in its focus on necessity, causal powers, and structures, makes it particularly well equipped for continuing these discussions.

Even though critical realist philosophy is now acknowledged infrequently in geography, most geographical research is at least implicitly realist. Antirealist and relativist approaches tend to be more preached than practiced – not surprisingly, for when it comes to doing actual research, we have to make claims about what is the case and assume that the world is not merely the product of our ideas, and that our theories are susceptible to empirical assessment. Intensive research designs, defended by critical realism, have become common and indeed orthodox in human geography, and at least implicitly, explanations are usually in terms of the causal powers of things. Recently, the emergence of the assemblage approach as a different form of realism invites dialogue with critical realism.

Critical Reflexivity and Social Work Practice

Abstract

Critical reflexivity is an epistemological position that brings together the social constructionist stance of reflexivity with the emancipatory goals of critical social science. Critical reflexivity is a vial precondition for critical reflection, yet not sufficient in its own right to activate the transformative deconstruction and reconstruction processes that critical reflection enables. The related concepts of reflection, reflexivity, and critical reflection will also be discussed. A critically reflexive stance is essential to further a critical social work agenda that is committed to social justice and human rights, despite the challenges presented by the contemporary, neoliberal context.

Introduction

Critical reflexivity is an epistemological position that brings together the social constructionist stance of reflexivity with the emancipatory goals of critical social science. It is a contested concept and often conflated with critical reflection. Critical reflexivity is a vial precondition for critical reflection, yet not sufficient on its own to activate the transformative deconstruction and reconstruction processes that critical reflection enables. In order to clarify the concept of critical reflexivity, the related concepts of reflection, reflexivity, and critical reflection will also be discussed. A critically reflexive stance is essential to further a critical social work agenda that is committed to social justice and human rights, because it enables critical reflection. These concepts are intimately connected as critical reflection can support social work practitioners to maintain a critically reflexive stance, despite the challenges presented by contemporary, neoliberal contexts that privilege objectivist paradigms including evidence-based practice and research.

Several writers have noted the distinct lack of consensus over definitions of reflection, reflexivity, and critical reflection (Fook et al., 2006), and critical reflexivity (Kessl, 2009: p. 305). As Askeland and Fook (2009: p. 289) state, "The terms reflection, reflective practice, reflexivity and critical reflection/reflexivity are often conflated or used indiscriminatingly, without clear definition." D'Cruz et al. (2007) similarly point out that "'Reflexivity' is often used interchangeably with other terms such as 'reflectivity' 'reflection' and 'critical reflection'" (see, e.g., Jessup and Rogerson, 1999: p. 176; Leonard, 1997: p. vii). Despite the complementarity of these terms, articulating clearer delineation between them is important for social work as they explicitly relate to improving professional practice and facilitating social change (D'Cruz et al., 2007).

Reflection

Reflection, also referred to as reflectivity (Fook, 1999), the reflective approach (Argyris and Schon, 1976; Schon, 1987), the reflective model (Pray, 1991), and reflective practice (Fook, 1996; Gould and Taylor, 1996), is "a process of thinking, of comparing and verifying for the purpose of learning about and improving practice, developing practice-based theory, connecting theory to practice, and improving and changing practice" (Fook and Askeland, 2006: p. 12).

The ideas about a reflective practice are usually traced to educationalists Argyris and Schon (1976) (later developed by Schon, 1987), who proposed a reflective process for uncovering hidden assumptions, particularly regarding professional learning. These authors were critical of professionals, identifying wide-ranging differences between their espoused theories and their actual practice (Argyris and Schon, 1976; Schon, 1987).

Schon (1987) questioned the usefulness of traditional approaches to building knowledge, and was dubious of the capacity of technical rationality to respond to the relationship between theory and practice. Some authors credit the earlier work of Dewey (1916, 1933) in developing current understandings of reflective practice (Mezirow et al., 1990; Fook et al., 2006: p. 8).

Whilst closing the gap between theory and practice is the ultimate goal of reflection (Schon, 1987), this may simply reinforce conservative practice. If a mental health practitioner espouses an acceptance of psychiatry, then deferring to medical experts that accept the status quo, and individualize social problems, is not identified as problematic practice by a reflective approach (Taylor and White, 2000). As Taylor (2013) explains reflective practice potentially occupies an apolitical space, over emphasizing the role of individual relationships and presenting an inadequate view of the impact social structures. This point clearly demarcates reflection from critical reflection, and some authors, suggest that such limitations can be enhanced by reflexivity (Lipp, 2007; Finlay, 2008).

Reflexivity

Reflexivity refers to one's capacity to look or act back upon oneself. The concept of reflexivity has figured prominently in epistemological debates concerning the relationships between knowledge, self, and society; and has emerged as a key concept in social constructionist approaches. The basic constructionist insight posits that knowledge of the world does not exist apart from people's involvement in it, which in turn shapes knowledge. Socially conditioned subjectivity decisively

affects knowledge production and truth claims (Seidman, 2013). Reflexivity is the self-conscious application of this insight, that social scientists apply to the truth claims of themselves and others.

One of the first writers to coin the term 'reflexivity' was Kelly (1955), who referred to the reflexive qualities of his work based on his acknowledgment of personal constructs (cited in Holland, 1999: p. 465). Later, in developing ethnomethodology, Garfinkel (1967) employed self-reflexive insight to show how the meaningfulness of statements and practices within academic disciplines are contingent upon the context of their production. This anticipated the contemporary movement from a social science based on establishing universal and objective knowledge to recognition of emergent, situated, and partial truths.

Gouldner (1970), in formulating a critical sociology as an alternative to systems theory and functionalism, contrasted its self-critical 'reflexivity' (explicating the social scientists' own assumptions and positionality in the construction of knowledge) with the contrived objectivism of mainstream sociology. Throughout the social work literature, reflexivity has been defined in myriad ways, yet most writers accentuate the impact and influence of the researcher on the research, especially motivations for undertaking the research, the design and methodology of the research, and how 'findings' are interpreted and presented, e.g., the privileging or exclusion of particular data in the final presentation of the research (Fook, 1999). This applies to both formal research in social work, and informal research that practitioners undertake on a daily basis, i.e., the knowledge that social workers produce about their practice and clients when interpreting situations to inform their responses to clients. Out of the multitude of ways that the worker could understand the client's narrative, how has the practitioner's values, assumptions, and interpretations shaped the information they have chosen to privilege, marginalize, or exclude in their presentation of the client's story in their case notes, research reports, or assessments? (This is discussed further below.)

Reflexivity exposes the researcher as the main instrument of data collection and a primary factor in the production of the knowledge (Fook, 2013). It asks researchers and practitioners to cease impersonating "'shamans' of objectivity" (Ruby, 1980: p. 154 cited in Smyth and Shacklock, 1998: p. 7) and transparently acknowledge that "the person producing the theory is included within the subject matter [s/]he attempts to understand" (Holland, 1977: p. 82 cited in Holland, 1999: p. 465). Instead of indulging the pretense of objectivity, and "engaging in futile attempts to eliminate the effects of the researcher … reflexivity enables researchers to…set about understanding them" (May, 1993: p. 75 cited in Smyth and Shacklock, 1998: p. 3) and use these to develop deeper insights into the social phenomena being explored (Morley, 2013).

Reflexivity is increasingly a compulsory requirement in evaluating qualitative social work research (Daley, 2010; Lipp, 2007). It appears in the research literature as an alternative to objectivist notions of reliability and validity, offering another approach to conceptualize ethical and epistemologically and methodologically sound research (D'Cruz and Jones, 2004).

Lipp (2007) argues that complexities associated with developing a clear, universal definition of reflexivity lie in acknowledging its use in different situations for various purposes. Whilst originating from research to "allow the researcher to examine how their research acts on the world and how the world acts on their research" (Lipp, 2007: n.p.), its applicability to enhance professional learning and social work practice is equally profound.

Reflexivity and Social Work Practice

More recently, reflexivity has emerged within the social work literature (Taylor and White, 2000; Powell, 2002; D'Cruz et al., 2007). For social work, reflexivity carries significant implications for informing research and critical practice. In the context of social work practice, being reflexive requires "an ability to recognize our own influence – and the influence of our social and cultural contexts …. In this sense, then, it is … about factoring ourselves as players into the situations we practice in" (Fook and Askeland, 2006: p. 12). Other writers further articulate: "Reflexivity is manifested in asking fundamental questions about assumptions generated by formal and practice theories; it addresses the multiple interrelations between power and knowledge, and acknowledges the inclusion of self in the process of knowledge creation in social work practice" (Lam et al., 2007: p. 91).

Paralleling this, Otto et al. (2009: p. 476) have drawn on work by Taylor and White (2000) to define reflexivity as a "primarily practical and ethical skill in social work … one that is fundamental for judging what is desirable and appropriate in specific circumstances by applying particular informal heuristics, rules and values, and the one that is particularly important in ambiguous and undetermined settings, circumstances, and contexts." Other important work on reflexivity in social work argues that reflexivity demands recognition of practitioners' role in engaging with, interpreting, and therefore recreating, and reproducing understandings of reality (Taylor, 2006).

Given that reflexivity highlights "he relevance of understanding how one's self can influence what and how knowledge is made, and can therefore shed light on how specific assumptions we make can arise from our own background and experience" (Fook, 2013: p. 6), it holds particular implications for practice, especially in relation to how social workers conduct assessments. In taking a reflexive position, social work practitioners choose from competing sets of discourses to assess the nature of issues presented by the person, group, or community they are working with. Each story the social worker collects has been assembled from a series of social constructions that are elevated to the status of facts and privileged in a coconstruction of the service user's particular account of their experience and the worker's engagement with it. Therefore, as the person to whom the stories are being told, the practitioner is implicated in constructing the service user's narratives (Frost, 2006). Developing a reflexive awareness about intrinsically political process of meaning making reveals that the practitioner's own subjectivity inevitably influences how they interpret and assess situations or behaviors.

The implications of this are troubling for the dominant objectivist paradigms that contend it is possible to isolate the object from the subject, the researcher from the researched, and the social worker from their assessment (Meinert et al., 2000).

That which can be known, from an objectivist epistemological position, is assumed to exist independently of the knower (Arnd-Caddigan and Pozzuto, 2006).

Conversely, reflexive practitioners recognize the impact of self on the knowledge that is created and factor this understanding into how professional decisions are made (Fook, 2013). Thus, the practitioner becomes the main tool of data generation during an assessment, which arguably contributes to a much deeper understanding of the service user's situation (Powell, 2002; White, 2001). Hence, the objectivist notion that assessments are fact-finding missions that can be undertaken as neutral and detached, technical activities is flawed (Rodwell, 1987; Fook, 2012). This type of reflexivity challenges the instrumental accountability inherent in evidence-based practice protocols and guidelines. For example, a child protection worker who undertakes an assessment using an objectivist/realist paradigm would attempt to gain information through the use of technical tools such as risk assessments, believing that it is possible to gain objective knowledge about reality that is untouched by their interpretation (Meinert et al., 2000; Loftus et al., 2011). In contrast, reflexive practitioners recognize that they are the key tool in any assessment process and so they scrutinize the ways their interpretive lens has informed the knowledge they produce.

When Kelly (1955 cited in Holland, 1999) first referred to the reflexive qualities of his work, he did so to differentiate himself from the behaviorists and psychoanalysts that he detested. This need for differentiation closely relates to the more contemporary debates that position reflexivity as a counter discourse to objectivist paradigms (D'Cruz and Jones, 2004); or reflective practice as a "new epistemology of practice" (Napier and Fook, 2000) and a refusal to reproduce the assumptions embedded within the natural sciences within social work practice (Taylor, 2013); and critical social work as an agent of critique and resistance to dominant discourses such as objectivism, evidence-based practice, and neoliberalism (Dominelli, 2004; Gray and Webb, 2013). Indeed, "In the context of the welfare state the definition of critical or radical social work – and therefore critical reflexivity – seem[s] to be relatively evident as 'oppositional' to the dominant paradigms" (Kessl, 2009: p. 312). Gray and Webb (2013) concur with this view, arguing that the new politics of critical social work take an innately political stance that that challenges capitalism and neoliberalism whilst facilitating emancipatory practices that address structural inequalities and injustices.

Critical Reflexivity

It is this political orientation that enables reflexivity to become critical reflexivity: by challenging and contesting the truth claims of dominant paradigms and the associated power relations; by elucidating the socially constructed nature of reality; and creating the conceptual space for alternative emancipatory discourses to emerge (Dominelli, 2004). For some writers, an analysis based on both modernist and postmodernist notions of critical social theory, implicitly, yet distinctively underpin their use of reflexivity in social work. These writers do not use the term critical reflexivity, but define reflexivity in critical terms. For example, Giles and Pockett (2013: p. 209) describe reflexivity as "an active process of critically analysing the knowledge and values that influence practice." Related to this, Ferguson (2003: p. 199) argues for a definition of reflexivity that draws on Giddens (1990) and Beck (1992) suggesting that reflexivity is "the ability to act in the world and to critically reflect on our action and in ways that may reconstitute how we act and even reshape the very nature of identity itself." Taylor and White (2000) refer to 'epistemic reflexivity' that promotes self-awareness of the impact of dominant discourses on tacit assumptions (Polanyi, 1966; Giles and Pockett, 2013: p. 209).

Gouldner (1970: pp. xiii, 489), writing prior to these debates, conceptualized "the historical mission of a 'reflexive sociology' as the 'transcend[ence] [of] sociology as it now exists." This representation of reflexivity invokes notions of fundamental transformations of the discipline, and is aspirational about social change. Lipp (2007) similarly devises a critical model of reflexivity that utilizes a form of reflective knowledge that takes account of technical practice and emancipatory dimensions of knowledge through critical theory. In addition, Freshwater and Rolfe's model of reflexivity implicitly incorporates a critical perspective including three types of reflexivity: a deep level of reflection; an account of the socio-political context; and reflection-in-action (cited in Lipp, 2007). Finlay (2008: p. 5) also depicts reflexivity as involving both 'personal reflection and social critique.' In her construction of reflexivity she asserts that "Reflexive practitioners engage in critical self-reflection: reflecting critically on the impact of their own background, assumptions, positioning, feelings, behaviour while also attending to the impact of the wider organisational, discursive, ideological and political context" (Finlay, 2008: p. 6). Such interpretations of reflexivity are clearly informed by the emancipatory goals of critical social work, despite the language of critical reflexivity not being explicitly used.

However, some discussions of both reflection and reflexivity have the potential to contribute to a critical emancipatory agenda, but are not inherently critical of their own volition (Lay and McGuire, 2009). Without explicit links to a critical theoretical analysis, these two concepts can become technicized and conservative (Taylor, 2013). For example, for Thomson (2013: p. 54) "the essence" of reflexivity in social work concerns "understanding how I am perceived by others. How others respond to me. And how I perceive myself working with others. It also concerns how I think and feel about my work, how I perceive myself in the job, and what the job means to me." This representation of reflexivity is neither politically conservative nor progressive and therefore, is inadequate for a critical social work project that "is primarily concerned with practising in ways which further a society without domination, exploitation or oppression" (Fook, 2012: p. 18). Whilst reflexivity involves an awareness of how a biographical lens shapes interpretations of individuals' constructions of their 'reality' over and above a range of competing perceptions, ultimately they need to be able to make decisions about which interpretations they privilege and why (Taylor and White, 2000). Critical theories provide an important framework on

which to base such judgments if individuals are committed to critical social work practice (Fook, 2012).

Critical Reflexivity and Social Work

This emphasis on the 'critical' is at the core of the difference between reflexivity and critical reflexivity. Although many authors have historically used an implicit critical lens when discussing reflexivity, the term critical reflexivity has more recently started to appear in the social work literature. Trevelyan et al. (2012: n.p.) position critical reflexivity as a principle aim of social work education, and argue that "critical reflexivity can be distinguished from non-critical forms of reflexivity by its emphasis on the socially constructed, power-laden nature of knowledge and subjectivity, and its embracement of anxiety and other difficult emotions in social work practice."

Kessl (2009: p. 307) positions critical reflexivity as a way for social work to locate itself within a 'transformatory agenda.' Kessl (2009) links critical approaches and reflexivity by drawing on Fook et al. (2006: p. 118) who connect the goals of social change to social workers that "are able to create critical knowledge which potentially challenges and resists current forms of domination." Kessl (2009) argues that a systematic approach to critical reflexivity in social work needs to be "augmented by and reconnected to a political, theory-based analysis of the actual contexts in which social work operates" and "need to be seen in connection with a fundamental transformation of the social order" (Kessl, 2009: p. 307).

Kondrat (1999) critiques the notion of reflexive self-awareness to develop critical reflexivity, which can be "taught as a skill … as a means for emancipation and self-actualization" (cited in D'Cruz et al., 2007: p. 77). Paralleling this, Brown (2012) posits critical reflexivity as a conceptual tool to identity the unintended, consequences of modernist discourses of power, which limits antioppressive practice. This is instructive for well-intentioned practitioners who seek to empower clients by giving them power. Brown (2012) highlights how assumptions embedded in modernist constructions of power as a commodity can inadvertently reproduce dominant power relations. In the example above, a lack of critical reflexivity could further disempower the client by reinforcing the idea that the client can only become empowered through practitioners' intervention, rather than their own actions. A critically reflexive practitioner would be more attentive to how the processes of their practice can be empowering, rather than assuming their intention will automatically produce an empowering outcome. Critical reflexive practitioners are more sensitive to unintended harm that social workers can cause through unreflexive practice.

Critical Reflexivity and Critical Reflection

This emphasis on the 'critical' is a key difference between reflection and critical reflection. Whilst some authors conflate the two concepts and use them interchangeably (e.g., Kondrat, 1999; Ruch, 2002), others debate whether they are the same (Parton and O'Byrne, 2000; Taylor and White, 2000), and some writers explicitly distinguish between them (e.g., Fook, 1999, 2012; Powell, 2002; D'Cruz et al., 2007; Finlay, 2008).

Both reflection and critical reflection are primarily identified as educational tools to improve congruence between professionals' use of theory and practice. However, more explicitly aligned with a radical politics, "[c]ritical reflection … is about understanding the technologies of power, language and practice that produce and legitimate forms of moral and political regulation" (Fook et al., 2006: p. 10). As Fook (2012: p. 113) claims: "The prime purpose of critical reflection is to unearth how we ourselves participate in discourses which shape existing power relations."

The critical component of critical reflection essentially challenges social inequalities that create injustice. This includes a key emphasis on power relations and domination (Gray and Webb, 2013). Critical reflection exposes the ways in which social work practitioners may be implicated in, or complicit with, dominant social power relations and structures that are unjust, inequitable, and/or undemocratic (Fook, 2012).

To critically reflect on implicit values and assumptions and scrutinize how these affect professional practice, practitioners can adopt a critically reflexive epistemological position. A critically reflective process cannot be undertaken from a position of objectivity. Critical reflexivity is a central component and necessary precondition of critical reflection. Both critical refection and critical reflexivity are underpinned by social constructivism, which fundamentally informs post-modernism. However, the key difference remains that critical reflexivity enables a practitioner to undertake critically reflective practice. Critical reflection incorporates a critically reflexive stance that activates broader transformative processes of deconstruction and reconstruction and takes account of critical postmodern theoretical frameworks (e.g., Allan et al., 2009; Fook, 2012); constructivist and experiential approaches to adult learning (Mezirow et al., 1990); and the reflective approach (Argyris and Schon, 1976; Schon, 1987) to generate theory inductively through critical reflection on practice.

Differentiation between critical reflexivity and critical reflection is contested, and some authors use the term critical reflexivity, as documented by Fook (2012) as critical reflection. Allan (2009: p. 1), in contrast, describes her auto-ethnographic study as one that used a "critically reflexive methodology to investigate [her] underlying assumptions about spirituality in social work and their impact on [her] practice with women survivors of sexual trauma." As in critical reflection, Allan (2009: p. 1) refers to analyzing 'critical practice moments' to identify 'existing and newly emerging assumptions' and refers to identifying the 'intended and unintended consequences of these assumptions' for her practice and engages in a 'deconstruction/reconstruction process' that develops new knowledge to inform her future practice. Hence critical reflexivity as defined here, is how others describe critical reflection.

Alternatively, other writers have presented reflection, critical reflection, and reflexivity on a continuum (Finlay and Gough, 2003). They contend that reflection stands at the

less sophisticated end of the continuum. "At the other end stands reflexivity: a more immediate and dynamic process which involves continuing self-awareness. Critical reflection lies somewhere in between" (Finlay, 2008: n.p.). The concepts of reflection, critical reflection, reflexivity, and critical reflexivity are presented, interpreted, and used differently, depending on the context and position of the author, and thus remain relatively elusive concepts, resisting universal definition.

Challenges to Critical Reflexivity in the Current Context

This article has discussed the development of critical reflexivity in social work, considering its implications for the practices of research and assessment. The related concepts of reflection, reflexivity, and critical reflection have been explored, demonstrating that the relationship between these concepts and critical reflexivity is contested and contentious. Regardless of the complexities and nuances between interpretations, most authors are in broad agreement that these concepts can support the emancipatory goals of critical social work.

The impact of neoliberalism has been well documented (Holscher and Sewpaul, 2006; Madhu, 2011) with the consensus being that neoliberal priorities can undermine critical social work objectives (see, e.g., Gray and Webb, 2013). These neoliberal priorities are augmented by imposing the practices of cost containment, standardization, compliance, an increased emphasis on risk assessment, and a quest of objectivity to eliminate uncertainty (Dominelli, 2004). This supports a view of social work that is less concerned with social justice and human rights, and more focused on individualizing social problems through developing technical proficiency in procedural knowledge that treats and manages apparently dysfunctional others (Holscher and Sewpaul, 2006; Madhu, 2011).

Within this context, many challenges exist for social work practitioners, researchers, and educators alike, who are committed to a critically reflexive stance. The dominant discourses are hostile toward this critical position, which is essentially constructed as at odds with the prevailing paradigms (Kessl, 2009; Gray and Webb, 2013). The debates about critical reflexivity, and attempts to develop further the concept, occur alongside policy mandates to make practice more scientific, objective, and evidence based (Taylor, 2013). Kessl (2009: p. 309) describes this as an "evidence-based practice or the 'what works agenda', that is designed to elicit a 'direct knowledge transfer' from positivist, experimental sources into the particular social work intervention" (Kessl, 2009: p. 309). Within this context, Kessl (2009: p. 309) argues that the concepts and practices of reflexivity (and critical reflexivity and critical reflection) are "under siege … and in danger of becoming more and more substituted by a technical-rational intervention agency which is still called 'social work', but represents a mode of intervention which is reduced to finding ways to achieve predetermined goals."

Arguably critical reflexivity and critical reflection are precisely what is needed to expose and oppose this situation: critical reflexivity to assist social workers to avoid becoming complicit in dominant power relations and being seduced by the 'tactics of governmentality' (Foucault cited in Madhu, 2011: p. 9); and critical reflection to reconstruct opportunities to create discretionary practice spaces for resistance and change. A lack of reflexivity, and particularly, critical reflexivity allows social work to function in a depoliticized mode (Taylor, 2013).

Both critical reflexivity and critical reflection are vital if social work is to strengthen a critical agenda. As Gray and Webb (2013) argue social work is charged with the responsibility to militantly challenge social injustices and the systems of domination that create them. The very acts of taking a critically reflexive epistemological position and developing the courage and humility to engage in critical reflection can in themselves, constitute undertakings of resistance to the dominant paradigms, and facilitate capacity to work toward emancipatory social change.

Abstract

This article examines the history and development of critical social work as an approach and a practice. It reviews the major historical perspectives on a critical social work approach and then outlines an approach to critical social work based on the major tenets of critical social theory, which includes postmodern thinking about how beliefs about how knowledge is made and is inextricably linked to power. Specific concepts (knowledge, power, language, and identity) and some specific ways that might translate into the practice of critical social work are also considered. These include critical reflection and deconstruction/reconstruction, problematization and research, narrativity, and contextuality.

Introduction

Critical social work practice is still developing as an approach, and there are varied perspectives on exactly what theoretical frameworks underpin it. In this article, I outline a framework using a conception of critical social theory which incorporates common aspects from several related contemporary theoretical approaches such as postmodernism and feminism.

History of Critical Social Work

The idea of a critical social work is relatively recent idea in the history of social work. It is an idea and an approach, which is still developing, and this means that there are many different meanings of the term.

Most writers would, however, agree that critical approaches to social work were born around the 1970s. They were based on the common critique during that era. Social work was characterized, like many other helping professions, as an agent of social control and the state. Contrary, therefore, to its stated helping ideals, the social work profession was seen to support the status quo, and social structures, which worked against the best interests of the very communities and people it purported to help. The social fabric, which justified and supported social inequalities, was viewed as the cause of social problems themselves, and so social workers could not really help people unless they assisted in dismantling the very structures which brought about social ills in the first place. Social change was, therefore, seen as an imperative of social work. This included challenging social oppressions, and empowering disadvantaged groups. Most criticism was directed toward casework, or individualized work, which was seen as founded on personal pathology. Individualized practice was seen as 'blaming the victim,' or as pathologizing and changing the people who were actually the blameless victims of a faulty system. This individualized type of approach was regarded as the major influence in the 1950s when the 'psychiatric deluge' swamped social work's initial conceptions of the 'person-in-context' (see Fook, 1993 for a full discussion of these terms and trends). These early criticisms were labelled as radical, and spawned a whole body of literature on radical social work, largely underpinned by Marxist analysis (e.g., Bailey and Brake, 1975; Corrigan and Leonard, 1978). These Marxist critiques tended to focus on macro level criticisms directed at material structural inequalities, embodied particularly in class differences. Much of this literature was subsequently criticized for its lack of attention to social work with individuals (Fook, 1993) and indeed for its lack of attention to practice per se.

There was room, therefore, for the radical critique of social work to become more sophisticated. There was a need to include the importance of gender, and gendered inequalities, as an additional aspect of the social structure. Feminist social work (e.g., Dominelli and MacLeod (1982) therefore developed in the 1980s as an important approach in addressing structural inequalities. Critiques of racist and ableist social work were also relevant to this (Dominelli, 1988; Oliver, 1990; Morris, 1991). This development continued, as further types of analyses were introduced which better theorized the nature and causes of social inequalities, and which allowed more sophisticated understandings of power, and the relationship of individuals to their social contexts. How these issues are theorized accounts to a large extent for different perspectives on critical social work which are in contemporary development.

Contemporary Understandings

There are now a number of perspectives on critical social work, which include: postmodern, antioppressive, structural, and new radical perspectives based on neo-Marxist analysis. What each of these shares is a commitment to understanding how power operates to sustain social inequalities. However the specific analysis used, and therefore the specific actions recommended, and the types of social changes called for, vary depending on the perspective taken.

Structural perspectives emphasize the importance of a structural analysis in social work practice, and are more materialist in their orientation (Allan, 2009). A key contemporary Canadian author in this genre is Mullaly (2007). Antioppressive approaches emphasize intersectionality and the imperative against oppression of all types (e.g., Dominelli (2002). Postmodern, and postmodern critical perspectives tend to include more complex analyses of power and difference, and therefore are useful for understanding the operation of exclusion at the everyday level. In social work, the major exponents of this

approach include Australians Healy (2000), Pease and Fook (1999) and Fook (2002, 2012). Newer perspectives including human rights, reflexive materialism, and critical race theory are covered in a volume, which includes authors from several different country contexts (Hick et al., 2005).

To a large extent, these varied perspectives are also associated with different country contexts, although there is some overlap. For instance, antioppressive social work is mostly written about from Britain, and is used to some extent in Canada. The term 'structural social work' originated from Canadian writers as noted above. Postmodern and postmodern critical perspective have largely been developed by Australian writers (e.g., Fook, 2002; Healy, 2000; Pease and Fook, 1999). Neo-Marxist approaches are having a comeback in the United Kingdom (e.g., Ferguson, 2008). In the United States, it is possible to argue that no specific approach exists, which even roughly equates to critical perspectives (Reisch and Andrews, 2001), although there is significant writing on empowerment (e.g., Simon, 1994). In the United States, there is some argument that critical perspectives have adhered most strongly with postmodern and social constructionist perspectives and it is noteworthy that the term 'critical' is rarely used.

I take a critical perspective, which incorporates postmodern thinking (Fook, 2002, 2012). My approach to critical social work practice is based on an understanding of critical social theory as espoused by Agger (2006). I cover this in the following section.

Key Concepts

Common Ideas Underpinning Critical Social Theory

Agger (2006) argues that there are common ideas shared by many social theorists (e.g., Foucault, Derrida, the Frankfurt School, feminism), which can be loosely grouped together as critical social theory. These include theories termed critical, postmodern, feminist, multicultural, and selected theories from cultural studies. He terms this a critical social theory "theory cluster" (2006: p. 4), which can be identified by seven common features (Agger, 2006: pp. 4–5):

1. Opposition to positivist understandings of knowledge making. Knowledge is not wholly 'objective' (i.e., simply constructed as an empirical 'truth' distinct from and outside of ourselves as knowing human beings). It is also actively made by people (e.g., researchers, theorists, practitioners). We, as members of society are all active participants in creating knowledge from our own social positions and perspectives, and cannot help but bring inherent value stances and biases. (The pronoun 'we' is used to refer to us all as people who are 'social subjects' i.e., as individuals who live in a society in which we participate to cocreate a shared sense of reality.) Knowledge cannot be value free.
2. The possibility of progress. Critical social theories build on the past and present to envisage and create a better future, to be achieved through social and political action. Critical social theory both raises awareness of oppression, and demonstrates the possibility of a different nonoppressive society. It not only seeks to facilitate social change, but also offers an analytical base for change.
3. Domination is both personal and structural, that is, people's everyday lives are affected by structural institutions and constructions such as gender and race.
4. Structural domination is also sustained at the individual level through false consciousness or ideology, (or discourse). Ideological or discursive thinking involves believing that there are ideas which are unchangeable, and therefore, taken-for-granted. Continuing to believe that these ideas cannot be changed therefore serves to maintain existing power relations and inequities. The role of critical social theory is to expose these beliefs (and false consciousness or discourse), thereby creating the basis for social change and transformation. By undermining false consciousness (and revealing the discursive functions of ideas, personal, and collective agency are enabled, bringing about personal and social change.
5. The belief that social change can be brought about by exposing false consciousness at individual levels implies voluntaristic (rather than deterministic) assumptions about people and the possibility of change. It opens the way for social changes to begin at the site of everyday life.
6. A dialectical relationship exists between structure and agency. Although social structures do influence everyday experience and lives, knowledge of how this happens also enables people to change the ways this happens.
7. The focus on the connection between everyday life and social structures also places responsibility on personal liberation, rather than on oppressing others in the name of distant future liberation.

Critical social work, based on the foregoing understanding of critical social theory, is therefore an optimistic approach, based on the possibility of personal and social change for the better, achieved through working together in dialogue. It can be summarized as follows. Critical social work is as primarily concerned with practising in ways, which work toward a society without domination, exploitation, and oppression. It involves understanding how structures dominate and also how people construct and are constructed by changing social structures and relations, recognizing that there may be multiple and diverse constructions of ostensibly similar situations. This understanding of social relations and structures disrupts dominant arrangements, and changes these so that they are more inclusive of different interest groups and perspectives.

Knowledge to inform this understanding is derived in different ways. Empirical knowledge is needed in order to understand how material structures shape lives. But processes of critical self-reflection are also crucial to ensure that dominant structures and relations are challenged in the way they are implicitly enacted in individual people's everyday lives. Communication and dialogue are necessary in order to ensure that diverse perspectives are included in forging new and inclusive ways of working. Thus, in a postmodern and critical social work both the kinds of social changes that are sought, and the ways in which they are enacted, are important. Outcome and process are integral to each other (Fook, 2012: p. 18).

Common Ideas Underpinning Critical Social Work Practice

This approach and these common theoretical underpinnings can be distilled to four key concepts, which are crucial to the

practice of critical social work, namely, knowledge, power, language, and identity creation.

Knowledge

The nature of knowledge and how it is generated are both technical and political issues in critical social work. What constitutes legitimate knowledge (and truth?); who accepts it as such; and what are the legitimate ways to generate and create it involves questions of hierarchies of knowledge and people (and therefore power).

It is important to note that critical perspectives recognize that knowledge can be generated by more scientific; means – commonly accepted methods which purport to discover the nature of 'facts' about our empirical world. However, these 'facts' may also be disputed because not everyone will agree with the methods used to develop them, or indeed, some 'facts' may not be relevant in different historical times, social contexts, or for different players. In this way, the more subjective nature of knowledge, and its generation, must also be taken into account. Knowledge in this sense can never be value free as it is necessarily influenced by who creates it, using what type of methodology, and in what context.

Reflexivity, or our ability to recognize how aspects of ourselves and our contexts influence the kinds of knowledge we produce and value, is an important concept in understanding how we as individuals can actively participate in creating and maintaining knowledge (which may or may not be relevant for other people in other contexts).

Additionally, to promote particular social actions, the knowledge that supports them is promulgated as factual, and therefore, universally agreed upon as true. To do this successfully, alternative perspectives are often suppressed or denied. Thus, knowledge and power are inextricably linked. In this way, views which are touted as 'true' may simply reflect the views of whatever group is dominant. This concept is highly relevant in understanding the operation of knowledge and power in professional life. For example, service users must often conform to a predetermined set of criteria about their situation and themselves as people, in order to qualify for legitimate services under particular policy provisions.

Furthermore, a similar process can occur in a more subtle way, with individual people in their personal and professional lives. For instance, most of us, base our actions, at the micro-level, on barely recognized assumptions, which mirror and support social arrangements. These may not be of our explicit choosing, and can work against our interests, or the best interests of the people we, as social workers, are working to assist. An everyday example of this is the decisions about how we behave in meetings. What culture(s) are we choosing to go along with when we decide where to sit, or who and what to support?

Critical reflection is an important ingredient in becoming aware of how we as individuals may create and support knowledge which excludes different (perhaps marginal) perspectives and which may therefore work to maintain social inequalities. I will discuss this in more detail in the last section on practice applications.

In social work practice, assumptions about knowledge are linked with assumptions about theory, what constitutes legitimate theory, and how it is made distinctive from practice. How we construct theory and practice, and the relationship between the two, is therefore a critical issue (Fook, forthcoming). How ways of understanding the relationship between theory and practice can be empowering or disempowering is an important site for social change.

Power

The concept of power, from a postmodern critical perspective, is seen as a dynamic force, which can be shaped and created differently in different contexts. The Foucauldian concept of power, as something, which is exercised, rather than something which is possessed, captures the essence of this idea. This conception of power as something, which can be made in social interactions is vastly different from the more commodified view, which seems to dominate accepted thinking. In dominant thinking, power is seen to reside with social position, and therefore, empowerment involves transferring power from one (more powerful) person to another (less powerful) person or group. This finite view of power is problematic because it infers that empowering one group necessarily involves disempowering another. This means that all situations, which involve empowering people are necessarily conflictual. However, in a postmodern view, this need not be the case. Different people and groups, starting from different social and power positions, may actively work together to create more power and in the process empower each other.

We discussed the relationship between knowledge and power above and it is important to remember that they should not be separated. A site for creating power and empowering others or ourselves, therefore, lies in how we conceptualize power, other people's power, and our own abilities to influence or act in a situation. This understanding of personal agency is crucial to a critical perspective on power.

Language

How we speak about our world and social phenomena is integral to our understanding of how we actively participate in shaping social structures and relations. Firstly, language involves labelling and categorizing which orders the phenomena we experience. Secondly, language functions to socially recognize phenomena – if something is not named, it is harder to speak or communicate about it, and therefore harder to legitimize or value it.

Furthermore, language is about more than words or phrases. It also includes implications about the phenomena we speak about. This is where the concept of discourse becomes important. Discourse refers to the ways of speaking about, and the messages, which are conveyed about phenomena. In this sense, it is about more than the specific words used in the language itself, but may involve nonverbal messages, implied messages, or messages communicated by the way a situation is structured physically. It may also be about more hidden meanings that are assumed in any given cultures, which are operating in a particular situation. For instance, when binary ('either – or' type) categories are used, it is implied that there is no other category or way of being. Often the two elements of the binary are pitted against each other, which suggests that they are mutually exclusive and sometimes opposed to each other. Hence, when we use binary categories, such as 'theory-practice,' we get the message that the two are very different and that much education and intellectual gymnastics go into

'integrating' the two. Such a split can support other binary categorizations (e.g., the split between academia and practice, or the split between research and practice). So where does 'practice theory' fit in such a split? In this way, it is easy to see how any more complex ways of understanding theory and practice may be easily left out. It is this leaving out of other perspectives, categories, or experiences which can also act as a form of power, to silence or devalue alternative views.

When we recognize the power of discourse, and also the power of dominant discourses to discount different perspectives, the concept of narrative becomes important. Narrative in a simple sense refers to the idea that whatever perspective is being touted represents that person's own story, told from their own social position, experience, and background. Thus, narratives may only represent one perspective, but may also represent a perspective, which has not formerly been recognized. This becomes particularly significant when people have not been allowed to tell their own narrative about themselves, their own biography, and identity. The concept of narrative is an important concept in applying the notion of discourse to practice. This will be discussed further in the last section.

Identity Creation

People's sense of themselves and who they are socially and personally can change over time, and can also include contradictions. Identity making involves both personal and social elements, and these can be reworked in the light of new experiences. This means that people do have the opportunity to remake a sense of themselves in relation to changing social contexts. It is possible that identities can:

- Change
- Be contradictory
- Be multiple

This perspective represents a major departure from the accepted way of understanding identity, which assumes that people hold an idea of themselves, which remains relatively coherent and constant over time. Indeed, it may sometimes be assumed that a stable identity is crucial to mental health. However, from a postmodern and critical perspective, we acknowledge that because identity is made in context, then an important aspect of coping in life may involve adjusting a sense of self in relation to changing experiences and contexts.

Since identities are changeable, it is important to understand how identities are made, and how these processes can be crucial in constructing social difference (and also in creating discrimination, inclusion, and exclusion). The process of 'othering' is a process whereby individual people or groups reinforce their existing identities by creating binary oppositional categories for other people or phenomena, which do not fit their preconceived notions. The 'other' group is by definition different. This type of thinking preserves and strengthens boundaries, and presumably, social comfort and certainty. This then forms a basis for discrimination.

Identity politics, as mentioned in relation to the concept of narrative, is therefore important in critical social work. How, and to whom, we accord power to make their own identities, and to coin their own language, becomes an important aspect of making social changes in our everyday lives. And how and whether we recognize and value these new categories are also an important part of critical practice. (see Fook, 2012: Chapter 6 for a fuller discussion of terms and concepts used in this section.)

Major Practice Applications

There are four major practice strategies which derive from the key concepts as follows: critical reflection and deconstruction/reconstruction, problematization and research, narrativity, and contextuality.

Critical Reflection and Deconstruction/Reconstruction

As discussed earlier, critical social work includes the notion that knowledge cannot be value free, and that the way knowledge is constructed, and the sorts of knowledge (theory), which is believed to be true, often reflects the exercise of power. In the practice of critical social work, it is therefore important to be able to uncover how this power operates through the knowledge that we choose to believe. Deconstructing language and ways of thinking to discover the operation of power is a method integral to critical social work practice.

In essence, deconstruction is a form of analysing discourses, or "uncovering the ways we talk about and choose to label experience, and how these shape experience" (Fook, 2012: p. 105). In other words, deconstruction involves uncovering the ways that power operates through the ways we label and interpret our experience. What preconceived labels or categories do we accept and choose to maintain? What are we leaving out? What is being distorted? What social rules are being affirmed or created? Whose perspectives are they and what do they have to do with power differences and inequalities? These are the sorts of questions, the answers to which help pull apart our own language and thinking to see how power operates in our own experience.

In the critical reflection model I developed (e.g., Fook and Gardner, 2007), the discourse being analyzed is a person's narrative about their own experience. Although there are many different perspectives on critical reflection, in critical social work practice, it is relevant to theorize critical reflection as a type of deconstruction of the narratives of personal experience, in order to uncover the hidden assumptions, which inform our practice, and therefore the hidden ways we participate in creating power. These can exist at a very deep and personal level, and uncovering these may help reveal how we can be complicit in supporting views or actions, which can also work against us or the people we as social workers are trying to help.

My model includes two stages (Fook, 2012): the first is deconstruction, where hidden assumptions are uncovered and examined; the second is reconstruction when assumptions (thinking) may be changed, and new ways of practice developed accordingly. This second stage of reconstruction must be an integral part of any critical social work practice. Deconstructing practice experience and thinking must be accompanied by concrete ideas of how practice can be rebuilt on the basis of what is discovered. Critical social theory in this sense provides an analysis, a way of enacting this analysis, and a blueprint for making social changes toward a more equitable and inclusive

society. These are contained in a structured and purposeful way, through critical reflection.

Problematization and Research

How we conceptualize and understand the daily 'problems' that we deal with as social workers is an integral part of the way we work as practitioners and researchers. Much has been made in the past of the way professionals 'pathologize' people and problems, often through a process of 'othering' so that any behavior or culture, which appears deviant from the norm is categorized as problematic. How then do we choose to understand and categorize social and personal issues in a way which respects them from an insider's perspective, but which also values the uniqueness of the perspective enough so that it can be acted upon effectively in a broader social context?

A first step is to see the task of conceptualizing and understanding an issue first and foremost as a research task. The aim of the research is to form a complex and deep understanding of the issue from the point of view of the person/people experiencing it. The task of the researcher is to stay open to discovering what this perspective is, and to use methods, which enable this to occur. This means starting with as little preconceived idea as possible, to listen to and accept the language of the person/people involved. It may also mean using communicative and investigative methods, which are most culturally comfortable or appropriate. These will vary greatly depending on your (the researcher's) gender, social context, age, ethnicity, and so forth, and those of the person/people you are interacting with. It may also mean accepting apparent contradictions (or even new viewpoints which differ vastly from your own), multiple perspectives, and changing interpretations (in line with the postmodern acceptance of fluid identities). Rather than glossing over or leaving out contradictions or changing viewpoints, the task of the researcher is to provide a communicable understanding of the issue or experience, which includes these differences. A complex picture (which derives from the person or situation itself) is aimed at, rather than a consistent or even balanced view.

The second task of the practitioner/researcher is then to mold this understanding into a narrative, which can be communicated to those who need to hear it. Who this audience is will depend on context. For instance, a social worker developing an assessment of a person to receive some form of social assistance may wish to use the language of the relevant policy, and choose to leave out aspects, which will diminish the person's chances of receiving the assistance. Or aspects that appear not to fit may be reworked in appropriate language. An audience of policy makers may need to hear about aspects of individual experiences, which sit outside the norm, so that their own critical thinking can be stimulated. A target group of social work colleagues might need to know about supporting statistics which will broaden their understanding of the social extent of the issue at hand, and give a context to their practice experience.

This process of coming to a comprehensive appreciation of social problems and issues from insiders' perspectives may be used equally well for assessment of individual or community situations. The key is to view the assessment not as an attempt to pathologize or fit the issue at hand into a preconceived category, but to be open to creating new categories or labels, and ways of communicating about the issue or situation, which suit the context in which the assessment is being made. This recognizes that conducting an 'assessment' is really more of a construction of a professional narrative, constructed to be effective, and relevant in a particular context.

Narrativity

The concept of narrativity refers to an understanding that a perspective on particular phenomena may represent only one perspective from a particular vantage point – social, historical, or political. Narratives, constructed as they are by particular people in particular contexts, function as a form of meaning making. Since the meaning is made in a social context, narratives also perform social functions. Narratives, like discourses, embody power. The principle of narrativity builds on this awareness to suggest strategies for destabilizing this power, and this provides the opportunity to remake it.

The principle of narrativity is related to concepts of discourse analysis, deconstruction, and critical reflection. However, it has special mention here as narrative therapy (see White and Epston, 1990) has become particularly well developed as a movement in its own right. The approach is based on the idea of examining and changing harmful narratives. In summary, it involves: identifying narratives, dominant, empowering, and disempowering; validating the positive ones and externalizing the harmful ones; and rebuilding alternative narratives and validating these further by creating an audience. Such an approach has been used successfully in many different fields of therapeutic work (Duvall and Beres, 2011). Narrative methods, however, can also be used more broadly, in work with communities and also in organizations, and are, therefore, an important component of the critical social worker's repertoire.

Contextuality

The principle of contextuality arises through recognizing that context influences much of analysis and practice in social work. Contextual practice (practice both within and with context) emphasizes several new ways of approaching practice (Fook, 2012: p. 162):

- Understanding the nature of the different contexts in which we work at different times and to developing relevant practice strategies. This may involve recognizing the role of a particular context in shaping certain attitudes or practices; or it may require adapting our ways of working to incorporate methods from past times or other contexts.
- Positionality – assuming a reflexively aware stance, simultaneously being able to see outside but also within contexts. This involves being able to understand and identify how we are inextricably part of a situation can also allow us to see outside it, and to use this dual awareness to be sympathetic to any resistance to change, but courageous enough to seek change.
- Working with whole contexts (rather than a number of disparate players or aspects). This involves the ability to see beyond the separate elements of a context to appreciate how they work together to create a dynamic whole. This enables working with how people work together, rather than working separately with the people themselves.

- Developing practice knowledge/theory that is transferable (not generalizable) between different contexts. This involves understanding that preexisting knowledge is not imposed top-down or from outside a situation, but rather preexisting knowledge is remade as relevant in new situations. New contexts are not made to fit preexisting knowledge, but rather preexisting knowledge is constantly remade from experience with new contexts.
- Reframing skills in contextual terms – developing 'contextual competence' is the ability to read the cultural climate of different contexts and to practice effectively with and within these contexts (Fook, 2012: p. 187).

Conclusion

Critical social work practice is still developing. Outlined here are some ideas about what it might look like using a conception of critical social theory, which incorporates common aspects from a number of related contemporary theoretical approaches (including postmodernism, feminism). An important concluding thought is that the practice of critical social work requires an openness to new experiences, people, and situations which allows engagement with each other in contexts of uncertainty which are often outside our control.

Definitions

Colonization of the lifeworld The system/lifeworld distinction is fundamental to Habermas's understanding of social coordination in modern societies. In such societies this coordination occurs, on the one hand through social systems, which embody instrumental knowledge, and on the other through the conscious steering of individual agents who are guided by norms that have been learned in the course of cultural evolution in reference to 'communicative action' and that have become embodied in the lifeworld. In Habermas's view the 'colonization of the lifeworld' occurs in modern capitalist societies as the instrumental and commodity logic of the capitalist system comes to dominate lifeworld relations, creating social pathologies. Within critical theory it is widely thought that such a 'colonization of the lifeworld' results in what Horkheimer describes as the 'fully administered life' and Marcuse identifies with 'one dimensionality.'

Discourse ethics This neo-Kantian form of ethical thinking is 'deontological, cognitivist, formalist, and universalist.' Rather than dealing with all questions of a good life, its focus is on problems of right or just action. Discourse ethics treats normative claims of rightness analogously to truth claims. In the place of Kant's categorical imperative, its principle is "only those norms may claim to be valid that could meet with the consent of all affected in their role as participants in a practical discourse" (Habermas, 1990, 196–7).

Ideology Ideology in the Left Hegelian tradition is not identified with 'worldviews' as it is in everyday language. Rather the term is used pejoratively to describe distorted worldviews wherein ideas are represented as universally valid or true when they in fact reflect particularistic interests of dominant social groups.

Ideology critique Rather than examining ideas as embodiments of value-neutral truths or looking for how they reflect universal characteristics of the transcendental ego, those engaged in ideology critique examine ideas and prevailing interpretive schema to see the ways in which they reflect the interests of socially dominant groups. In the tradition of critical theory, it has typically been maintained that unveiling the particularistic interests behind such allegedly universal ideas serves to empower social agents to enact social change.

Immanent transcendence In a formulation by Hiliary Putnam that Habermas approvingly cites, "Reason is…both immanent (not to be found outside of concrete language games) and transcendent (a regulative idea that we use to criticize the conduct of all activities and institutions)" (cp. Habermas, 1992, 139). The concept of immanent transcendence, also often referred to as intermundane transcendence, implies in Habermas's terms that "validity claims raised hic et nunc and aimed at intersubjective recognition or acceptance can, at the same time, overshoot local standards…." (Habermas, 1988, 15).

Recognition Recognition is the English translation of the German term 'Anerkennung,' which serves in Hegel's *Philosophy of Spirit* as a goal toward which mind is moving in the process of cultural and social evolution. In Hegel's system, upon achieving recognition, mind comes to see itself in all of its creations. Recently, Axel Honneth has made a reformulation of this Hegelian idea the centerpiece of his critical theory, maintaining that it is anchored in human anthropology, establishing a pretheoretical desire for (1) care, (2) self-respect, and (3) self-esteem. The concrete understanding of what recognition in these specific areas entails is worked out in human interactions under specific historical and social conditions.

Rational reconstruction Rational reconstruction is a method of theory construction that aims to formulate implicit, pretheoretical knowledge, practical know-how, or rules needed for engaging in social practices or communication. Habermas views rational reconstruction as allowing 'weak transcendental arguments,' which, however, are fallibilist. Often such reconstructions aim to disclose universal or species competencies or rules. Among other things, pretheoretical knowledge in the existing forms of intramundane transcendence is made explicit in reconstructions (see Habermas, 1990, 32f.).

Abstract

Critical theory is a philosophical social scientific research program that engages in explanation against a background of normative interests. While Max Horkheimer conceived of the original research program as an attempt to revive a form of nonorthodox Marxism, Jürgen Habermas, the main representative of the second generation of critical theory, has developed a research program on the basis of a rational reconstruction of competencies of communicative action while increasingly assimilating the work of American pragmatists. Current critical theorists – besides Habermas – see a need to reconstruct the original research program, while retaining its orientation as a normatively driven theory.

Introduction

'Critical theory' refers first and foremost to the social scientific research program guided at its inception especially by the vision of Max Horkheimer, who was an early director of the Frankfurt Institute for Social Research, later known as the 'Frankfurt School.' Horkheimer envisioned an interdisciplinary research program, at once philosophically normative and empirically based. The research program was conceived as an attempt to revitalize Marxist analysis, while rejecting orthodox Marxism and critically appropriating especially the work of Freud, whose approach was viewed as complimentary to Marx's in that it too was both socially scientific and oriented toward human emancipation. Rather than focusing exclusively on issues of economic redistribution, critical theorists further emphasize 'psychological, cultural, and anthropological sources of unhappiness' (Bronner 2011, 29). The further development of the work of critical theory is represented especially in the social research program of Jürgen Habermas and the moral philosophical work of Axel Honneth.

More recently, the terms 'critical theory' and 'critical social inquiry' have been used to refer to various approaches in the social sciences and humanities that have family resemblances to the original work of the Frankfurt School. Such critical theories include critical race theory; some feminist work in the philosophy of science; the socially critical work of Michael Foucault, Jean Baudrillard, and some other postmodern social theorists; and the work of various contemporary nonorthodox Marxist social critics. Given the lack of a specific unifying research program, it is most appropriate now 'to speak of critical theory in the plural' (Müller-Doohm, 2004, 294).

Since its onset critical theory has normally shared certain characteristics with Marx's criticism: (1) Critical theorists have viewed themselves as continuing the modernist project. (2) They have linked theory and practice, both noting the effects of social practices on theory formation and formulating theory with a view to emancipating the marginalized. (3) Most often they have proposed dialectic theories. (4) They have operated with a view that there are forms of immanent transcendence available that facilitate critique. Consequently, an effective critique of society is not reliant on external criticism, but is possible using norms already accepted within a given society. (5) They have engaged in ideology critique, attempting to unveil the ways in which prevalent ideas in many social domains illegitimately facilitate the control of some groups by others. Unveiling such ideology has been viewed as having the potential to empower those who see the ideology to engage in social transformation. (6) Most critical theorists have assumed that there are pathological features specific to capitalism that prevent the self-actualization of many members of society and that changing the economic system will eradicate many of the pathological features of modern life.

Axel Honneth, the current director of the Frankfurt Institute for Social Research, expresses a widely held view among critical theorists that the original program of critical theory is no longer plausible and that in order for the tradition to continue, it must be reconstructed. In Honneth's view, any useful reconstruction will need to take up themes of Left Hegelianism, which differentiate critical social inquiry from other forms of social criticism: A viable critical theory will show how reason is embedded in history (the idea of immanent transcendence), indicate how the lack of the full realization of reason in society leads to social pathologies, and demonstrate that humans have some form of 'emancipatory interest' in overcoming such social pathologies. Such a reconstruction, integrating several of the elements noted above, is what he envisions as the task for the heirs of critical theory in the twenty-first century (cp. Honneth, 2009).

Intellectual Backgrounds

The Frankfurt School

The Frankfurt Institute for Social Research was founded in 1923 as a Marxist think tank under the direction of the economist Kurt Albert Gerlack. Important members and participants in the early work group included two of the most important 'Western Marxists' from the early twentieth century, Karl Korch and György Lukács, along with Friedrich Pollock, who continued to contribute to research in the school after Horkheimer assumed directorship of the institute in 1931. Only Lukács's work is read today. While the institute's early work was 'orthodox Marxist' in orientation, once Horkheimer's assumed the directorship, the institute moved to a Freudian-Marxist influenced position. Under Horkheimer's direction, the institute published the *Zeitschrift für Sozialforschung*, the journal that served as a conduit for seminal papers reflecting the research program. During the Nazi regime, the institute was relocated to Columbia University. In 1949, Max Horkheimer and Theodor Adorno returned to Frankfurt to reopen the institute there. Various thinkers who had become identified with the Frankfurt School (as the school came to be known under Horkheimer's direction) went their separate ways throughout this period of exile. Throughout the tumultuous history, the originally shared research program largely broke down, and even Horkheimer increasingly distanced himself from it.

The interdisciplinary early research in the Frankfurt School included Theodor Adorno's work on aesthetics and on the authoritarian personality; Herbert Marcuse's writings linking material structures to the phenomenological structures of human thought in *Ontology and the Theory of Historocity* (1932); Friedrich Pollock's work on 'state capitalism,' a term that referred to the administration of the economy even through the apparatus of the state, which is lead by instrumental logic of capital and results in conditions of alienation and exploitation; Leo Lowenthal's sociology of literature and mass culture; and Otto Kirchheimer's and Franz Neumann's writings on philosophy of law. Eric Fromm was formally a part of the institute for a short time until 1940, and his treatment of authoritarianism in *Escape from Freedom* (1941) and later work after a break from the institute largely reflect many of the concerns of the research program. Walter Benjamin never formally belonged to the Institute for Social Research, but he was intensely involved with several of the institute's members, especially Adorno.

Horkheimer's Early Research Program

The main outlines of Horkheimer's initial research program were clearly articulated in essays throughout the 1930s, including 'Materialism and Metaphysics' (1933) and 'Traditional and

Critical Theory' (1933). In general, Horkheimer is critical both of what he views as irrationalist forms of hermeneutical thought as well as the scientistic tendency of positivism, which reduces reason to its instrumental function and brackets rational reflection on social questions. In contrast to 'traditional theorists,' Horkheimer thinks that the rational development of ideas does not occur in a normative-free space but against a background of real material interests. Rejecting the view that knowledge develops unhinged from interests and values, critical theory aims not just at an abstract truth but at a theory that can 'liberate human beings from the circumstances that enslave them' (246). The themes of Horkheimer's early program are Left Hegelian. In fact, he emphasizes the need for a dialectical philosophy that recognizes 'that the free development of individuals depends on the rational constitution of society' (Horkheimer and Adorno, 1972, 246). Horkheimer's view unites theory and practice, for one by aiming theory at practical (normative) results, but for another by unmasking traces of human practices (and norms) in the world of theory.

Horkheimer's critical philosophy and social theory does accept in broad outlines the Kantian and Hegelian view that a full scientific understanding of the world requires an understanding of the subjects that produce knowledge. While in Kant, this famously entailed an analysis of the universal categorical structure required for generating human knowledge, in critical theory the very structure of human thought determinations itself is viewed as socially conditioned and as especially related to the economic base of society. Therefore, the mental schema necessary for an interpretative experience of reality are not viewed as ahistorical or transhistorical elements of a transcendental ego but as part of a socially conditioned and historically malleable mental architecture that, among other things, reflects power schema in the social world. As a result of this, any sufficiently critical philosophy will entail not just an understanding of the prevalent views of science, and not just an understanding of thought schema used by human subjects (the focus of the 'critical' studies of rationality in German idealism), but more fully an understanding of the social conditions that come to be reflected in the thought schema necessary for generating theory and in the theories generated with such mental schema.

The approach does retain something of the attempt to German ideology to think the entire system of reality. However, Kant's category teaching gets replaced by a sociology of knowledge – and in particular one at that entails ideology critique or a 'hermeneutics of suspicion' while aiming at social emancipation. Rational reflection on the social basis for the mental schema is thought to be a necessary supplement to reflection on the results of science. Therefore, the products of law, art, media, and science are not to be evaluated only on discipline-internal criteria. While there is social learning according to discipline-internal standards, it occurs always against a backdrop of human interests and values.

Moreover, critical theory tends to entail that more rational forms of social interaction are a prerequisite for more adequate forms of theory. In short, the counterpart to the idea that bad social practices become mirrored in theoretical ideas, and in the very theoretical schema used in the appropriation of knowledge, is that good ones do as well. Therefore, in the early work an impulse is found that adequate theory requires more humane social practices. Truth is linked to justice. Indeed this is a view already implied in the work of Hegel and Marx.

The Negative Turn in Horkheimer and Adorno

Although Horkheimer set the agenda for the first-generation critical theoreticians while in Frankfurt, he progressively was influenced by Adorno, and by the time of the writing of the Horkheimer–Adorno coauthored *Dialiectic of Enlightenment* (published in mimeograph form in 1944 and as a first-edition book in 1947) and Horkheimer's *Eclipse of Reason* (1947) much of Horkheimer's original agenda had been set aside, as he had become increasingly negative about the possibilities for escaping the 'iron cage' of instrumental rationality in late capitalism.

The *Dialectic of Enlightenment* aimed to provide 'the discovery of why mankind, instead of entering into a truly human condition, is sinking into a new kind of barbarism' (Horkheimer and Adorno, 1972, xiv). While Horkheimer and Adorno by no means come to reject rationality and indeed go so far in their support of the enlightenment as to maintain that 'freedom in society is inseparable from enlightenment thinking' (xvi), they view the *de facto* course of the development of reason as having resulted in the domination of nature and of man. They thus engage in their work in the *Dialectic of Enlightenment* for the somber reason that it is the demand of critical reason 'to take up the cause of the remnants of freedom' even if it seems 'powerless in the face of the great historical trend' (Horkheimer and Adorno, 1972, xi).

While indicating that the instrumentalization of reason and the administration of all of life do indeed come to a head in capitalism, *Dialectic of Enlightenment* differs from the earlier work of the institute because it offers not a local analysis of forms of thought and problems in late capitalism, but a world-historical view. The roots of the process of the instrumentalization of reason and of the present crisis have a much older origin. In fact, early myth is even implicated in the process as a first step toward the emancipation from nature.

A description of the rationalization process of Western civilization – building on Weber's work – is central to the book, accompanied by an explication of the domination of nature and of man that results from this. While the enlightenment has aimed at autonomy, in its *de facto* development it 'radiates disaster triumphant' (Horkheimer and Adorno, 1972, 1) and has even become 'totalitarian' (Horkheimer and Adorno, 1972, 4). The instrumentalization of reason leads to a fully administrated world and 'makes humans into beasts' (Horkheimer and Adorno, 1972, 185). The end result, as they discuss it, could have been written by Heilbroner or other later environmental survivalists: "Either the human species will tear itself to pieces or it will take all the earth's fauna and flora down with it…" (Horkheimer and Adorno, 1972, 186).

Despite this prevailing pessimism, the book and this period of the writing of Horkheimer and Adorno more generally do contain a dichotomy between the radically negative characterization of the results of the domination of instrumental rationality and a quite different positive and expanded characterization of a potentially emancipating reason, which always exists as an alternative to the instrumentalizing concept, as a parallel running enlightenment that could control the

domination of man and nature, but that never manages to do so (cp. Wiggershaus, 2007, 332ff.).

While Horkheimer turned increasingly to theology in his late work, Adorno, in *Minima Moralia: Reflections from Damaged Life* (1951) and *Negative Dialectics* (1966), if anything, became even more pessimistic. His view progressively became that contemporary life is so damaged that the most that can be hoped for is that individuals engaged in nonpurposive activity – in art, in acts of love, in unselfish giving – achieve some 'human cells within universal inhumanity' (Adorno, 2005, 31).

Current Knowledge

Habermas

Habermas, the most well known of the second-generation critical theorists, viewed this negative turn and abandonment of the earlier social scientific research program as unfortunate. Noting that there was no existing social research program when he arrived at the Institute for Social Research (Wiggershaus, 2007, 544), he did begin to revive critical theory in alignment with the scientific aspirations of the earlier work, even while developing this in a quite different direction than the first-generation theorists. His work is encyclopedic, like that envisioned as programmatic for the early Frankfurt School, including work on numerous aspects of the history of philosophy, ethics, political theory, philosophy of law, philosophy of mind, psychology, and religion. His most influential writings, however, focus on communicative reason. His own research program, which he views as a fallibilistic continuation of the enlightenment project, has developed in part through the critical appropriation of work in German social theory, American pragmatism, and Kantianism.

While Habermas does take up the view implicit in Horkheimer and Adorno's earlier work, he, in contrast to his former teachers, engages in a justification of the enlightenment project. Like the earlier critical theorists, Habermas is critical of positivism for the ways that it views scientific knowledge as interest-free and of hermeneutics and its heirs for its relativism. He thinks that in the end both traditions undermine rational thought about ethics – the former tradition because 'ethical thought' is not scientific, the latter because it views ethical commitment as based on decisionism. In his early epistemological work *Theory and Practice* (1963) and later in *Knowledge and Human Interest* (1968), he draws up a position counter to both positivist and hermeneutic theories while working through various issues that arose in *The Positivist Dispute in German Sociology* (1969/1976). In particular, under the influence of American pragmatism, Habermas argues for the interest-laden character of all knowledge, maintaining that knowledge in the various human domains is rooted in three 'anthropologically deep-seated interests': the interest in instrumental control, in understanding, and in emancipation. Each of these anthropologically seated interests tracks to a particular intellectual domain. The interests in instrumental control is at the basis of the development of the natural sciences. The interest in understanding serves as the basis for the human sciences. The interest in emancipation serves as the basis for moral-practical knowledge. Herewith he slices up intellectual activity in alignment with Dilthey's view that there are different methods for the natural and the human sciences, while adding an 'emancipatory interest' as the basis of a third form of knowledge. This latter interest is especially evident in ideology critique and psychoanalysis, both of which aim at the emancipation of the individual from social and individual psychological burdens.

Although Habermas later abandons this anthropological oriented theory of this early work for a more Kantian quasi-transcendental grounding of knowledge in reference to forms of social action based in linguistic competencies, he retains the intellectual division of labor of the earlier schema. Habermas employs a method of rational reconstruction in which he elucidates the presuppositions for various types of human action. These allow a form of 'weak transcendental' argument. However, unlike the Kantian program, the rational reconstruction results in falsifiable claims, not elements of a 'first philosophy' in the tradition of the philosophy of the subject, which Habermas thinks brackets social inquiry. The forms of action in Habermas's mature theory are viewed as preconditions for the type of social action that we already *de facto* engage in. In our social life, we do not merely use reason in a rational purposive manner (in action oriented toward success). We also give and take reasons in an attempt to reach agreement about what is right (in action oriented toward consent) (cp. Habermas, 1984, 285). This act of giving and accepting reasons entails various presuppositions. We presuppose our own free agency. We presuppose that there is one world that we are referring to. We presuppose that there are better and worse answers not only to scientific but also to the ethical/social questions we pose.

More specifically, communicative action involves three types of validity claims, which for their part are tracked to three types of speech acts: constative speech acts entail a claim to truth, regulative speech acts contain a claim to normative rightness, and expressive speech acts entail a claim to truthfulness (Habermas, 1984, 319–20). In the claim to normative rightness, later called the 'discourse principle' (Habermas, 1998, 41), a claim is justified only if all could agree to it in an unconstrained dialogue, or an ideal speech situation. Those who do provide or accept reasons for actions are thought to necessarily presuppose these to make sense of their own reason giving. This latter form of action, similarly to the earlier 'emancipatory interest,' tracks to the 'subterranean enlightenment' of Horkheimer and Adorno's *Dialectic of the Enlightenment*. In Habermas's view, it is not merely subterranean and forever unable to gain control over rational purposive action. Rather, it too has permeated civil society, and it influences law and politics and provides real possibilities for emancipation.

In the fuller rational reconstruction of our competencies, Habermas argues that in the act of giving and accepting reasons for action, we *de facto* assume that we are agents, responsive to reasons. We assume active stances toward our desires and are not merely passive victims of them. We assume that through a process of rational reflection, we are able to come to 'reflectively endorse' certain actions, that is, that we can commit ourselves to them as being rationally worthy of support. Finally, we understand this process of reflectively endorsing ideas not as merely playing out in a human subject, cut off from the social world, but rather as subjects engage in reflection with other reflective agents in a social world where certain norms

and reasons are considered acceptable (cp. Baynes, 2004, 202). In contrast to the view that these presuppositions for action adhere merely because we are heirs to the practices of a given tradition, the quasi-transcendental view sees such presuppositions as universal. In this way, Habermas can avoid falling back into a mere hermeneutics or a relativist pragmatism a la Rorty.

Throughout his career, Habermas attempted to avoid relativist conclusions like those he sees as inherent in hermeneutics, yet he does not for that dismiss hermeneutics, but rather critically appropriates it. In Habermas, the giving and taking of reasons plays out in the lifeworld, where the interpretive schema of our traditions play a fundamental role. They serve as backdrops for viewing the world and imagining possible social action. While we cannot escape this backdrop, neither are we completely bound by it. Rather, it functions by establishing constraints and enabling conditions for our action and our interpretations and explanations of the world. Habermas's view is that individuals not only actively appropriate ideas from their traditions but also critically reflect upon them. In the give and take of rational argumentative processes, we are always open to the fact that justifications might challenge the prevailing interpretations of the world, as embodied in our traditions, and lead to a revision of the interpretive framework against which we view the world and against which our wills are formed.

Habermas and German Social Theory

Habermas's theory does develop through a critical appropriation of various stands of social theory and philosophy of the late twentieth century besides hermeneutics. In contrast to the proponents of hermeneutics, he argues for a thicker view of reason. He also argues that their focus on linguistic 'interpretation' renders hermeneutics a form of idealism that fails to duly account for the ways in which social institutions come to embody certain rational norms and values and to influence our lives.

Besides appropriating elements of hermeneutics, Habermas also integrates work from sociological systems theory, although, in the end, adopting a version closer to that of Parsons than of Parsons's German student, Niklas Luhmann, the most important figure in European social systems theory in the late twentieth century. While Habermas recognizes that system dynamics establish something like hard-wired tendencies for certain domains, like Parsons, he still maintains a fundamental role for human agency.

Luhmann's version of systems theory views social systems as functioning on the model of cybernetic theory. Social systems are organized wholes that assimilate information from the world according to simple binary codes; in this way, they simplify the world in such a manner as to facilitate social coordination. Each of these systems works according to its own code. The economy operates on the codes of profit and loss, while the knowledge system operates on the code of true and false, and democratic political systems operate on the code of government and opposition. In Luhmann's view, we must simply recognize these as independent domains, and in fact we have no reason to choose one system over another.

Because the position ultimately offers an extremely truncated space for human agency, and indeed flies in the face of how we understand ourselves as human agents, Habermas contrasts system developments with those in the lifeworld.

While there is a decoupling of system and lifeworld in modern societies, which contributes to social efficiency, learning occurs not only with a view to instrumental action that comes to be embodied in systems but also in reference to communicative action in the lifeworld, allowing democratic, as opposed to merely technocratic social action coordination. It is in the lifeworld where symbolic meaning systems are negotiated that allow collective control over systems.

While Habermas sees a place in the world for social systems, he sees a threat in their overstepping their rightful bounds. A fundamental problem specific to the late capitalist social world is that the system of the economy becomes increasingly pervasive in all spheres of life. The logic of that system comes to dominate lifeworld interactions, and the 'iron cage' of instrumental reason – emphasized by Weber and taken up by Horkheimer and Adorno – thus becomes a dominant filter through which we interpret all social life as we experience the 'colonization of the lifeworld' by the logic of the capitalist economy. This is a tendency that must be overcome if we wish to have autonomy.

Habermas and Postmodernism

Because Habermas views social learning also as occurring in the lifeworld, Habermas is more optimistic than Horkheimer and Adorno, and also the postmodern critics of rationality. In Habermas's view, the postmodern critics have a truncated understanding of what reason is. In the end, they exhibit a sensitivity to difference and to the dominance of instrumental reason, but they undermine any criteria that might be available for supporting their own views that the dominance of instrumental reason is a problem to be taken seriously. Habermas thus views these critics of reason as ultimately involved in a 'performative contradiction.' They argue for the weaknesses of reason, generally viewing the enlightenment tradition as merely the most recent of numerous forms of mythology. If this is the case, there is no need to pay heed to their rational arguments at all. If the enlightenment system of reason giving is a mythological system like any other, then why prefer it to other myths? Habermas's own view is that in giving and accepting reasons, we already do presuppose the transcendental conditions that were earlier outlined. If we fail to do so, we are left with decisionism. Among other things, we thereby also undermine the self-understanding we have as agents.

Procedural View of Reason and Justice

Against postmodern critics, Luhmannian systems theoreticians, and hermeneutists, Habermas argues for continuing the enlightenment project. Rather than arguing for a substantive view of rationality, for example, based in human anthropology, he ultimately argues for a procedural view of reason. Rational procedures are those that promote 'unconstrained dialogue' aimed at understanding. This requires that no individuals be prevented from taking part in the processes of social decision making. A rational, and consequently just, society thus has social institutions that facilitate the collective control of life. In Habermas's view, this provides the basis for the acceptance of

certain procedures of justice in society but does not provide for the mutual acceptance of metaphysically laden thick views of a good life (cp. Habermas, 2005).

This emphasis on the procedural view of reason and justice is characteristic of Habermas's political writings and ethics. His view is that in a pluralistic postmetaphysical political reality, we cannot base a political program on shared thick views of the good. Rather, communicative action can at best secure procedures for social decision making that make a place for all individuals affected by social decisions. This leads him to support a form of deliberative democracy that is inclusive, embracing contemporary values of religious liberty and respect for diversity. He does not presuppose that we come to the social dialogue with a ready-made understanding of what is in the general interest, but that through fair, inclusive procedures we can reach conclusions about what legitimate social and political actions should be undertaken.

While Habermas has increasingly emphasized the importance of specific religious and communal identities to action in civil society and that these are not to be bracketed from in democratic societies, he, like Rawls, continually maintains that the legislative process itself should only reflect those considerations that can be put in language of the public sphere – the language of reason – amenable to all regardless of their thicker views of the good.

Current and Emerging Directions

Contemporary Critical Theory after Habermas

Axel Honneth

The main strands of critical theory today view the first-generation research program as requiring a fundamental reconstruction. Axel Honneth, probably the best known living representative of critical theory after Habermas, has long made strong charges against the Frankfurt School, going so far as to say that "critical theory appears to have become an intellectual artifact" (Honneth, 2009, 336) and noting that "as an interdisciplinary endeavor to critically diagnose social reality, this tradition ceased to exist some time ago" (Honneth, 2007, 63). Still, he thinks that the tradition can be usefully reconstructed for our times.

For one, Honneth argues that first-generation critical theorists largely simply presupposed forms of 'intramundane transcendence' for which the Hegelian tradition had attempted to provide a metaphysical grounding. A major task for critical theory is now to justify the standards of critique in society. Habermas has taken this up, but so have Honneth and others among the new generation of critical theorists.

As Honneth sees it, two major lines have emerged in critical theory in reference to the question of immanent transcendence, each characterizing one of the main tendencies in critical theory today (Honneth, 2007, 66). On the one hand, there is the negativist turn, following Adorno. The most well-known theoretician of this ilk is Foucault, especially in his middle-period writings. There he indicates that we are always subject to exertions of power in oppressive ways but indicates no way to escape this situation. Another of the postmodern critical theorists is Jean Baudrillard, who emphasizes the impossibility of escaping mere simulation in the contemporary world in which symbolic forms are proliferated and reproduced, in the end freed from their referents (Honneth, 2007, 67). Such postmodern forms of thought wield an important critique of power aligned with fundamental tendencies of Frankfurt School critical theory, in particular integrating the genealogical critique traceable back to Nietzsche (cp. Honneth, 2009, 243–253), yet they fail to secure the basis on which critique is possible. Honneth argues, however, that the type of genealogical element found in this work – which examines ways that norms have lost their original meanings and serve as instruments of oppression – is integral to any critical theory today (Honneth, 2009, 51ff.).

On the other hand, there are attempts, like Habermas's, that provide a justification for rational critique. Honneth's work builds on Habermas's as he attempts to show the types of virtue that are necessary for individuals to participate in the ideal forms of dialogue that Habermas envisions and as he argues that "the normative presupposition of all communicative action is to be seen in the acquisition of social recognition" (Honneth, 2007, 71). While Honneth builds on Habermas's theory in fundamental ways, Honneth is critical of Habermas for failing to give an account of individuals' experiences of injustice. This severely limits Habermas's ability to shed light on how social conflict plays a role in the shaping of norms in the lifeworld.

This is fundamental, Honneth argues, because progress in our moral understanding is pushed along by social conflict, and the social protest that in part drives this social learning process occurs not because individuals have a sense that communication is distorted, but because their senses of justice have been violated. Honneth argues that the feelings of injustice emerge because of a lack of recognition – manifest as affronts to dignity, honor, or integrity. It is such feelings of 'social disrespect' that drive protest.

Honneth's system thus elevates the phenomenological moral experience of those involved in social interaction, hereby providing an alternative to Habermas's linguistic-based justification of moral theory. Where Habermas takes a Kantian turn, Honneth takes a Hegelian one, making the concept of recognition the basis of his justification of the moral-critical point of view. He also notes, however, that he is not yet able to justify that the desire for recognition is basic to communicative action. Consequently, his theory is based on an assumption that a desire for recognition is pretheoretically anchored, as a part of basic human anthropology. In the course of the sociohistorical development, specific understandings of what recognition entails are worked out.

The point he would like to emphasize is that when entering into communicative relations, we bring expectations of social recognition (Honneth, 2007, 72). Fundamental to human life is not merely our interest in our individual lives but also an interest in our collective life. We form our identities in intersubjective processes, and our self-actualization occurs not in isolation, but in society. Honneth specifies three dimensions of this concern with recognition in a way that facilitates insights into moral theory from an ethics of care, Kantian or other rights approaches, and the neo-Aristotelian capabilities approach. These dimensions entail (1) 'emotional concern,' (2) 'rights-based recognition,' and (3) 'the social esteem of individual achievements and abilities,' respectively (Honneth, 2007, 74). Recognition in each dimension is necessary for successful self-development.

Nancy Fraser

Other important critical theorists are involved in endeavors similar to Honneth's, focusing on moral argumentation. While Honneth claims that his recognition concept includes issues of redistribution, Nancy Fraser argues that it systematically underplays the significance of economic issues. In short, Honneth extends the concept of recognition 'beyond all recognition' when claiming that it encompasses economic concerns in the same way as the 'Old Left' (see Fraser and Honneth, 2003). Fraser, for her part, develops a model based on a tripartide concern for matters of (1) recognition, (2) redistribution, and (3) representation. Honneth's theory, she argues, reflects the turn toward a politics or recognition that occurred with the 'New Left.' This turn from traditional concern with economic issues did indeed help in the understanding of social justice, but one should not for that downplay economic justice. Beyond these two concerns, Fraser argues, in part assimilating Habermas's work, it is also fundamental that there is fair access to political and cultural processes that shape the framing of political and social issues. In these processes, among other things, we delimit the concerns for justice (cp. Fraser, 2008, 2, 5).

New Issue Areas

Gender issues, along with issues of environmentalism and global governance, are among the areas of special importance in developments in critical theory in recent years.

Gender Issues Reflected in Feminist Philosophy of Science

Seyla Benabib and Nancy Fraser have taken up gender issues in developing critique that clearly identifies with the tradition of critical theory. However, specifically in the area of gender studies other interesting work clearly aligned with critical theory has been done in philosophy of science by theoreticians who do not specifically claim identification with the tradition of the Frankfurt School, but whose work provides a clear example of critical social inquiry. In particular, the works of Sandra Harding and Helen Longino are exemplary of this. Like first-generation critical theorists, both Sandra Harding and Helen Longino counter the positivist view of the value-neutral character of observation, emphasizing that observation occurs against historically contingent background conditions. As Longino notes, "Scientific knowledge…is a body of diverse theories and their articulations onto the world that changes over time in response to the changing cognitive needs of those who develop and use the theories" (Longino, 1996, 276).

It is a mistake, Harding similarly argues, to view the 'facts' produced in the sciences apart from the conditions under which they are produced, for there are social conditions at play at every step in the knowledge formation process. "Culturewide (or nearly culturewide) beliefs function as evidence at every stage in scientific inquiry; in the selection of problems, the formation of hypotheses, the design of research (including the organization of research communities), the collection of data, the interpretation and sorting of data, the decision about when to stop research, the way results of research are reported, and so on" (Harding, 1993, 69). Longino highlights the historical malleability in the standards for research: "The kind of knowledge a community seeks, the purposes for which it seeks it…guide the development of the community's standards" (Longino, 2001, 188). Both thinkers reject the view of the 'unconditioned subject,' who is 'guided by context-independent and value-neutral methodological rules,' and they focus on epistemic communities: since there are no raw facts, but only facts produced against the background of social beliefs, needs, and interests of an epistemic and social community, we must evaluate the background conditions in such a community. This constitutes the 'logic of discovery' that Harding discusses.

Specifically, given the subjective elements in science, Harding and Longino emphasize that scientific institutions would do well to integrate more women at our current juncture. Inclusive scientific communities allow the background conditions to be more adequately examined and allow shared values and interests to emerge. Far from distorting objectivity, introducing a 'women's perspective' thus can improve the quality of science. Concrete examples of this are not lacking, for instance, in anthropology, where opening the field to women researchers unveiled the presence of male biases in research that systematically ignored potential roles of women in the technological development of society by focusing on the development of weapons rather than household utensils, and in sociobiological research, where women working in the field unveiled similar distortions. These arguments in general are more forceful in the human than in the natural sciences.

Much of the work of these feminist philosophies of science corresponds with the basic impulses of the Frankfurt School. They view science and society in some ways as 'co-constituting' of each other, and carry out a hermeneutics of suspicion with the intention of empowering those who gain this knowledge to bring about changes in the institutions of science so that it can better overcome systematic distortions to knowledge that can occur in light of male power structures dominant in society.

Environmental Concern

Critical theorists are also increasingly working in environmental philosophy and environmental political theory. Here in particular two strands of work in environmental philosophy build on the traditions of critical theory. One strand (see Biro, 2011) views Habermas's theory as largely lacking the resources needed for adequate reflection on the environmental problematic. These theoreticians criticize Habermas for viewing our approach to nature as by necessity instrumental, anchored as this is in the view that rational-purpose action is basic to constative speech acts themselves. They also emphasize his lack of general concern with the environmental problematic, which he only addresses in passing references. Consequently, they would like to go back before his work to critically appropriate many of the ideas of the first-generation Frankfurt School. While there are many dimensions to this work, one of the most important is that they view critical theory as providing a sophisticated view of the social construction of reality that steers between the naïve realism found in many varieties of environmental thought and an overly linguistically oriented social constructivism found in others. While, like Kant, critical theorists view 'nature' as constructed, in contrast to Kant, they

emphasize that the human subject that constructs that 'nature' is also constructed: "Neither subject (society, the individual) nor object (nature) is something given; it is always connected with its opposite" (Görg, 2011, 52). As such theoreticians see it, it is thus important to shape societal relationships that are shaping the subject and the subject's understanding of and interaction with the world. Many of these critical theorists attempt to identify the effects of the 'capitalization of nature' on how nature is being constructed in environmental politics – for example, on how capitalization results in the 'selective treatment' of environmental issues in late capitalism (Görg, 2011, 60). In general agreement with Walter Benjamin, Görg argues a point that many of these environmental philosophers accept: "it is not nature we need to master, but rather our societal relationships with nature – that is, we need to control the impact those relationships have on nature" (Görg, 2011, 47).

Another stand of environmental philosophy, represented by John Dryzek and Robyn Eckersley, is more optimistic about the possibility of extending Habermas's model so as to make a place in our political and civic life for those who represent all the 'communities of fate,' including nonhuman members of it, along with members of future generations. Extending critical theory along these lines, John Dryzek argues for a form of strong ecological modernism, which restructures capitalism so as to become environmentally sound. This entails (1) strong changes to the infrastructure and economic systems to make them more responsive to ecological concerns; (2) more open democratic decision-making procedures, also with increased communication about ecological issues; and (3) concern with international aspects of environmental and development problems (Dryzek, 2005a, 173ff.). Given that ecological concerns are not nationally contained, state policies and state publics must take up concerns that transcend their own borders.

Globalization

Much of the work on green politics that is coming from critical theorists draws on further work on deliberative democracy and on the global public sphere that has been done by Habermas and other critical theorists such as James Bohman (2010) and Seyla Benhabib (2006). A lot of this work focuses on how transnational civil society can be used to shape public opinion, determine national policies on transnational matters, and affect the policy of the United Nations (UN) and other transnational governmental bodies.

Most of these critical theorists, like Dryzek, follow Habermas in rejecting David Held's call for a world parliament as impracticable and propose instead forms of transnational cooperation among states, regional governments, and civil society organizations, along with attempts to influence the existing transnational governmental bodies such as the UN and the European Union. Dryzek is skeptical that enough can be done within states, noting 'all liberal democracies currently operate in the context of a capitalist market system' and are consequently 'greatly constrained' in determining policies (Dryzek, 2005b, 634). Consequently, rather than focusing on the state or on extending the mechanism of the state globally in accord with Held's model, Dryzek proposes a grassroots strategy in global civil society, emphasizing the importance of nongovernmental organizations and informal international networks (cp. Bohman, 2010, 42–44). Here, Dryzek emphasizes the value of radicals in the public sphere. Since the radicals are not working within the system of government, they are not as easily forced to compromises, and can more easily speak the truth to power (Dryzek, 2005a, 218–227). It is radicals in the public sphere, he maintains, "who have made the running in instigating change in ideas and attitudes, which extends to those who do not vote for green parties, still less join more radical green actions" (Dryzek, 2005a, 222). Of course, if these attitudes cannot change institutions, then there is little hope that the response will be sufficient.

Taking up global governance in reference to the environmental problematic and other issues is certainly important in globalizing critical theory. However, even the perspective on these issues that is dominant in Frankfurt School-oriented critical theory is largely Eurocentric. Although many in Asia, the Middle East, Africa, and Latin America are strongly influenced by critical theory and are working largely as critical social theoreticians, European and American scholars rarely engage in exchanges with these thinkers. A couple of the theoreticians who have begun looking beyond the Euro-Anglo world and are engaged in critical social inquiry in ways that may facilitate a different kind of global critical theory are Susan Buck-Morss (*Thinking Past Terror: Islamism and Critical Theory on the Left*, 2003) and Eduardo Mendieta (*Global Fragments, Latinamericanisms, and Critical Theory*, 2008).

Changing in Focus or Emphasis over Time

Beyond the shifts in emphasis in reference to gender issues, environmental concerns, and issues of globalization, three of the other biggest alterations in critical theory have occurred in reference to Marxism, pragmatism, and methodological pluralism.

The End of Marxism?

While critical theorists are critical of the view that often is thought to be implicit in Marx – namely, that a shift in the means of production would bring an end to nearly all forms of psychic discomfort – they still have always traced many forms of social pathology to a basis in the existing economic form of existence. Marcuse spoke of the conditions of capitalism as causing one dimensionality, and restricting the type of pleasure possible in a postscarcity society. Horkheimer and Adorno spoke of how capitalism leads to a 'fully administered life.' Habermas has long spoken of the 'colonization of the lifeworld' leading to distorted communication.

While there is still a tendency to perceive the dominant forms of life in capitalism as impinging on as full of an expression of reason as is possible, few of the Frankfurt School-influenced critical theorists today speak of a full-throated socialist alternative to capitalism. More typically they write of the need for 'reflexive modernization' (Dryzek, 2000, 163–66), 'economic restructuring' (Fraser and Honneth, 2003, 75), or the 'taming' of capitalism (Habermas). This shift has accompanied the shift toward a more optimistic view – evident most

clearly in Habermas – that there have been advances in moral-critical reasoning accompanying the development in the forms of instrumental technical mastery. Consequently, the moral and political ideas in modern political and legal institutions are not viewed as merely entailing potential for domination but are seen as also embodying potentials for emancipation.

This general turn toward liberalism in Habermas-influenced critical theory can be contrasted with the recent work of various leftist theoreticians proposing a renewal of the 'communist idea' (see the selection of papers in *The Idea of Communism*). Such work runs the gamut from Zizek's farcical embrace of Stalinism through Susan Buck-Morss's look at 'historical pragmatics' to Vattimo's plea for a kinder, gentler, 'weak communism.' While some of this work goes much further in the support of violence than the Frankfurt School ever did, some of it clearly aligns with the basic reformist tendency that has characterized most thoughts of critical theory.

Pragmatist Critical Theory

While first-generation critical theory was critical of pragmatism – with Horkheimer viewing it as having no theory of society as a whole – there has been a turn to pragmatism in the course of the development of critical theory. Habermas began referring to his own views as 'Kantian pragmatist' in the 1990s, but he had long been influenced by pragmatism. *Knowledge and Human Interests* had already integrated the essentially pragmatic idea of various interests at the basis of knowledge generation. Further, the idea fundamental to Habermas's consensus theory of truth – that truth is what we are bound to agree to over the long run – is adopted from Pierce. In addition, Habermas integrated work from Mead on the social construction of individual identity in the give and take of dialogue in a social world (cp. Strydom, 2011, Chapter 3). Indeed, Habermas has come to see pragmatism as the one school of thought among the Hegelian legacy that shares his own spirit of liberalism. He notes, "Pragmatism constitutes, besides Marx and Kierkegaard, the third Young Heglian tradition, and the only one that convincingly develops the liberal spirit of radical democracy" (Habermas 2002, 228; see Strydom, 2011, 64).

Steven White and James Bohman emphasize a 'pragmatic ethos' at the root of contemporary critical theory that underlies the acceptance of plural perspectives, the social character of the self and of scientific inquiry, along with the connection between scientific inquiry and the community (cp. White, 2004; Bohman, 1999). Both thinkers suggest that a critical social theory informed by such a pragmatic ethos should be more 'problem-driven' than the current 'theory-driven' or 'method-driven' inquiry characteristic of critical theory, including Habermas's version. This move toward pragmatism does give rise to various methodological questions.

Methodological Issues

Methodological Pluralism

While Habermas is widely known for emphasizing that the possibility of an ultimate consensus is viewed as a presupposition to communicative action, he has always also recognized that the path to this consensus is paved with debate and disagreement. Still, his position has been that since we rationally are trying to explain and interpret the same social world, we should expect ultimate convergence in the best possible explanation. This is a point of contention both within critical theory and beyond. Many critical theorists emphasize that critical social inquiry is not in a position to replace existing research programs in the social sciences so much as to work in connection with them (cp. Honneth, 2007, 63; Bohman, 1999). Given the pluralism in the social sciences, however, this entails that we might well expect multiple viewpoints to prevail within the social sciences indeterminately. Longino formulates one position on this debate, noting her approach "does not preclude the possibility of some single all-encompassing theory being the final result of inquiry nor does it preclude the possibility of multiple accounts" (Longino, 2001, 140). Indeed, if philosophy is no longer able to stand as judge over the sciences, but must work as stand-in, and do that within a fallibilist framework, this seems a likely conclusion. While the work that a philosopher does as a stand-in should not render philosophy so impotent that it cannot, for example, criticize social scientists for working with methodologies that are themselves not falsifiable, it does not appear to leave philosophy so empowered that it can justify an ultimate judgment about whether a consensus will emerge in the social sciences, above all given the rather nonideal conditions in which theorizing does occur.

Explanation and Interpretation/Theoretical and Practical Reasons

The issue of methodological pluralism is related to questions of the separation between forms of understanding and forms of explanation in Habermas's formal description of his theory and in the work of other critical theorists. Habermas has come under considerable criticism for implying that there is such a neat division of labor between the various fields of inquiry, with certain interests tracking to specific domains (Detel, 2007). A myriad of questions emerge. For one, is not explanation used in the 'interpretative sciences' the domain evidently of understanding? Do not social scientists formulate hypothetical deductive theories as a matter of course so that the claim that they operate fully under the influence of a different method is clearly wrong from the outset? (cp. Mantzavinos, 2006). Similarly, are not interpretations a part of the background for theoretical explanations in the natural sciences? In short, it appears that in his theoretical writing Habermas illegitimately divvies up intellectual tasks in a too neat and unrealistic manner.

While a generous reading of Habermas is that he sees these spheres, not as completely isolated from one another, and indicating that rightness claims can have nothing to do with truth claims, or that strategic or instrumental reason can have nothing to do with communicative reason, but as indicating an 'idealizing supposition' generally applicable for certain kinds of action (Baynes, 2004, 198), this will not dissolve all the issues. Connected to this division of the intellectual tasks are questions about whether rightness and truth claims are best treated as creating a fundamental division between practical and theoretical reasons at all, or whether it is more suitable to

follow Dewey in embracing a more unified view of reason, which sees the tasks in these domains not as separate but as existing on continuum (cp. Berstein, 2010, 188ff.). Therefore, along with questions about the justification of the separation between explanation and understanding are questions about the separation of theoretical and practical reasons.

Further Questions of Habermas's Moral Theory

A more general criticism of Habermas's moral theory has concerned its formalism since the Kantian turn. In short, many have questioned how useful the idea of unconstrained dialogue is, or more specifically whether it is utopian. Since we will never have a condition of absolutely unconstrained dialogue, there are obvious difficulties knowing what normative claims might be reached under such an ideal speech situation. Does it get us further than Rawls' thought experiment of the veil of ignorance? Many of the criticisms along these lines have the character of Hegel's criticisms of Kant. While these criticisms come from some opponents to Habermas's project, they are also waged by those critical theorists who think that Habermas needs a still stronger pragmatist turn.

A further influential criticism of Habermas's ethics has been leveled by Ernst Tugendhat, a German ethicist who, like Habermas, develops a Kantian-influenced moral theory. Tugendhat (1994) famously questioned whether Habermas's ethics involves him in a form of circular reasoning. According to Habermas's argumentation, rational dialogue requires unconstrained agreement, a condition that for its part can only be guaranteed if the participants in moral dialogue have equal possibilities in social dialogue. This requires rather robust conditions of social equality. Consequently, the egalitarian form of society that Habermas desires to achieve is simply elevated to a presupposition for rational dialogue. As Tugendhat expresses this, the form of the argument is essentially if p and q, then q. If rational dialogue is only achievable with equality, then equality – a goal of Habermas's theory – is *de facto* not justified but presupposed. It is written into his definition.

While the force of the argument is not to be denied, it is clear that Habermas does not simply aim at generating equality from his moral argument. Rather, unconstrained dialogue allows decisions to be made about an entire plethora of moral questions in a fair and open manner. Further, the radicalism of the equality demanded by Habermas's theory is not entirely clear. Indeed, it is not clear that the theory entails a more fundamental form of equality than Rawls's theory, or even Tugendhat's.

Views of Reason and the Linguistic Turn

Further criticisms concern Habermas's linguistic turn. One issue is that it has neglected the experience of human subjects. Honneth is among those calling for a more phenomenological turn within critical theory, indicating the need to refer to first-person experience to make sense of movements of social justice that he thinks stand behind the growth in our moral-practical knowledge. Various proponents of the philosophy of the consciousness similarly criticize Habermas for the lack of a place for elements of the philosophy of consciousness, noting that even the work in rational reconstruction that Habermas engages in presupposes the privileged access that cognitive subjects have to their own experience, despite Habermas's rejection of such elements (cp. Freundlieb et al., 2004). Quite recently, Matthias Vogel (2012) has presented challenging arguments to all of the views of reason that focus solely on linguistic competencies for failing to provide the means needed to explain nonlinguistic human communication, such as that which occurs in music, art, and communication with babies. Related to such criticism is the question of whether Habermas's critical theory has not more generally ignored our embodiment. The characteristic ignorance of critical theorists of work in philosophy of biology and neurophilosophy is not unrelated.

Conclusion

The idea that critical theory does not provide a theoretical basis that can be definitively formulated, but that it should be reconceived to deal with emergent sociohistorical realities and developments in the sciences, was embraced even by the earliest generation of critical theorists. When publishing the English language volume *Critical Theory* in 1968 Horkheimer himself noted that many of the ideas "no longer have any direct application" and that "to relate them properly to the present situation requires careful reflection" (Horkheimer, 1982, v). Indeed, the original program itself was sensitive to the historical nature of thought, viewing the frameworks for interpreting reality and against which explanations occur as reflective of shifts in material conditions of reality. Those involved in critical theory today would thus be well served by accepting Horkheimer's warning of the dangers of a "thoughtless and dogmatic application of the critical theory to practice in changed historical circumstances" (Horkheimer, 1982, v).

Most critical theorists today are of the view that critical theory needs to be reconstructed. Greater attentiveness to our embodiment, to subjective experience, to particular emerging social issues, and to the developments in the natural sciences will mean that critical theory will develop not only in directions differing from first-generation critical theorists but also in directions differing from Habermas's influential form of critical social inquiry.

Critical Theory: Contemporary

Larry Ray, University of Kent, Canterbury, UK

Abstract

This article is a discussion of the formation of contemporary critical theory with particular reference to the work of Habermas and Honneth and the debates that have arisen from these. They have both extensively recast the earlier critical theory of Adorno and Horkheimer through Habermas's communicative turn and then Honneth's theory of recognition. However, core themes of critique of domination and the conditions for an emancipated form of life continue to inform contemporary debates.

Critical theory is a term adopted to situate social philosophy and theory in the heterodox Marxist intellectual tradition of the Frankfurt School (especially Adorno and Horkheimer). Contemporary theories might develop different analyses from earlier versions, although a critical theory will aim to explore the conditions of both domination and critique of obstacles to emancipation and a 'good society.' Critical theory was originally associated with the Frankfurt Institute in the 1930s, the key figures of which included Max Horkheimer, Theodor Adorno, Walter Benjamin, and Herbert Marcuse. Critical theory embodied the Hegelian and psychoanalytic reorientation of Western Marxism during the 1930s in which theory was transformative, rather than contemplative, engaging with historical processes to enhance human emancipation (Horkheimer, 1972). Unlike more orthodox Marxism, it accorded central significance to culture (including mass media), authoritarianism, science and technology, and gender. Central to their thinking was the apparent eclipse of the revolutionary proletariat in the wake of Stalinism, Nazism, and mass consumption capitalism. Many of these themes, expressed for example in Horkheimer and Adorno (1973), were to become central to social theory some 25 years later. Many of its original themes (such as the demise of the historical subject, critique of the culture industry, attention to psychosocial processes, critique of technology, science, and domination) have entered mainstream social theory and it might be less clear now what its particular contribution is. Nonetheless, these themes remain important foci of critical theoretical debate about the possibilities for a better society.

Of central concern for earlier critical theorists was the materiality of capitalism and its distorting effects on critical consciousness, rational reflection, and the capacity for organized political opposition. When theorists turned to areas previously neglected by Marxism, such as Adorno's extensive critiques of the culture industry, mass media, and positivist epistemology, the critique of commodification retained central importance. This was moreover a critique informed by an aesthetic and affective sensibility, which Adorno hoped would "lend suffering a voice" (Adorno, 1974, p. 247). Further, while the aesthetic experience of critical art offered the 'tremor of the possibility' of a better society (Adorno, 2003, p. 14), popular culture was commodified and produced according to the logic of mechanization. By contrast, later the critical theory of Jürgen Habermas refocused attention on issues of the public sphere and emancipation, linguistics, contemporary sociological theory, and the limits of radical critique. Habermas's work has been controversial. Some of the most interesting critiques of Habermas have come from feminist critical theorists, who share his commitment to the explication of power, knowledge, and morality, but differ with him on other issues. This has, in turn, raised questions about the limitations of Habermasian universalism as opposed to more embodied and concrete concepts of the self and discourse. Subsequently, Axel Honneth (b. 1949) who is currently Professor of Philosophy at the University of Frankfurt and Director of the Institute for Social Research has shifted the metatheoretical foundations of critical theory from communication to recognition and moral experience via a return to the Hegelian concept. He treats recognition as a need that is anthropologically grounded in the constitution of society. Here, 'recognition' is used in the Hegelian sense as a concept to describe the birth of consciousness through mutual recognition between two subjects. More recently, Honneth has provided an extensive discussion of recognition aiming to show the motivational and normative role recognition can play in stimulating social movements. Following Hegel and G. H. Mead, Honneth identifies three 'patterns of recognition' necessary for a positive relation to self. These are love, rights, and solidarity, which are discussed later.

Contemporary Critical Theory

Jürgen Habermas (b. 1929) claims that it was not his intention to continue the work of the Frankfurt School, which he says was a response to historically specific experiences of fascism, Stalinism, and the Holocaust (Anderson, 2011, p. 31). Nonetheless, he has been the dominant figure in contemporary critical theory and is widely regarded, along with some contemporaries, such as Albrech Wellmer, Karl-Otto Apel, and Oskar Negt as representing a 'second generation' of their thinking. Central to his work has been the aim to specify the conditions under which human life would be free from domination. He has, however, criticized many of its earlier claims. He regards Horkheimer and Adorno's apocalyptic despair as having ignored the

'unfulfilled potential' of Western modernity to expand rationality and democracy (Habermas, 1987, p. 113). They too readily accepted a Weberian nightmare of an iron cage of total domination, in which philosophy could only keep alive the possibility of a better society while lamenting the lost opportunity for emancipation (Benhabib, 1981). Further, Habermas has effected a comprehensive project critically synthesizing contemporary sociology and philosophy that not only abandons Adorno's aversion to theoretical wholes but also positively incorporates theorists whose nondialectical and 'affirmative' systems thinking Adorno rejected. This notably includes Talcott Parsons who is central to Habermas's development of a theory of communicative action in the 1980s (Habermas, 1987). Nonetheless, for Habermas, the very possibility of critique must presuppose the existence of rational criteria of a better society against which the present is being judged (Habermas, 1987, p. 113). He aims to recover and explicate this potential, to which end he has undertaken an elaborate reconstruction of the grounds of everyday communication.

Communicative Turn

Habermas attempts to invigorate critical theory by embracing the real achievements of bourgeois democracy while salvaging the project of modernity specifically through a mobilized public sphere, revitalized public discourse, and personal involvement in politics. Habermas's early work focused on the constriction of the public sphere (*Öffentlichkeit*) and democratic deliberation by technocratic politics and commercial mass media. (The public sphere is seen as a discursive arena that facilitates citizen debates, deliberation, agreement, and action where individuals are able to freely share their views with one another and see the effects of their deliberations in a process that approximates a participatory democracy.) Although less apparent in his later work, the encroachment of democratic will formation was encapsulated in his highly influential distinction between two social orders, of lifeworld and system. The former is the sphere of communication and culture, mediated by norms and language. The latter refers, using Parson's concept, to forms of social 'steering' by money and power, which are not available to normative discourse. While Habermas insists that the market and state are essential in modern societies, the notion of steering media appear no longer as benign processes reducing social complexity but if unleashed threaten to undermine communicatively secured solidarities. There is then a continual tension along the boundaries of lifeworld and system where new social movements arise, potentially pushing back systemic intrusion and opening spaces for democratic deliberation. An example would be environmental protests over nuclear reprocessing that open debates about the rationality and morality of projects previously driven by technological and financial criteria. This approach was closely linked in the 1980s to 'new social movement' theories, the underlying assumption of which was that new conflicts no longer arise in areas of material reproduction, are not now channeled through parties and organizations, and can no longer be alleviated by compensations that conform to the system. Rather, "the new conflicts arise in areas of cultural reproduction, social integration, and socialization" (Habermas, 1981). However, while this approach was highly influential and cognate to the emerging identity politics in the same period, the idea of postmaterial conflicts looks less relevant in a period of economic crisis and rapidly growing national and global inequalities, a view which is reflected in more recent debates. Thus, the critique of the disembedding and unleashing of markets and political power in the early twenty-first century has been made more with reference to global neoliberalism and, for example, how the weak publics of transnational or global civil society have failed to generate levels of postnational solidarity that would even begin to approximate those of nation-states. This disembedding of economic and political power reflects how social solidarities have not kept pace with the globalization of power, law, and money (Brunkhorst, 2007).

In a further departure from the earlier critical theory, Habermas identified potential emancipatory practice not by appeal to putative agents of change (such as the proletariat) but through 'universal pragmatics' – a move that was signaled by his critical engagement with Peirce in Habermas (1973). Later, Habermas sees in the pragmatism of Pierce and Dewey a postmetaphysical philosophy that can address the very foundations of the critique of domination (Ray, 2004). This is because for Habermas the potential for rational agreement is present in sociolinguistic rules of communication. He uses Chomsky's linguistics and Austin and Searle's theory of speech acts to reconstruct communicative rules, arguing that the elementary units of communication (speech acts) involve validity claims that are 'naively accepted' in conversations. For conversations to occur, one assumes agreement about grammar and illocution, that is, one recognizes something as a promise, an assertion, an order, etc. Similarly, judgments about the comprehensibility of actions involve evaluations as to whether good reasons have been provided. Although moral choices are often regarded as matters of personal conviction, Habermas agues that the requirement to provide good reasons, subject to public scrutiny, renders these choices 'capable of truth.' The evaluation of moral choices is comparable to the evaluation of empirical claims in that both the proffered reasons are subject to critical testing (Habermas, 1992, p. 76). Thus, Habermas seeks a practical and cognitive basis for critical theorizing.

These are not timeless linguistic structures, but unfold historically through the formation of posttraditional (modern) worldviews. Unlike Marxist theories, which view social development as the succession of modes of production, Habermas's theory refers to stages of cognitive and moral learning, which parallel childhood development. Premodern forms of moral authority involve conventional attachments to externally given value systems, underwritten by sacred beliefs. Echoing Kant, 'maturity' involves postconventional distance from rules and the capacity to evaluate and argue whether adherence to a moral injunction is appropriate. Successful posttraditional sociality institutionalizes new levels of cognitive and moral learning, thus normative structures are the 'pacemaker of social evolution' (Habermas, 1979, p. 120). Modern worldviews dissolve sacred authority into rational justifications of morality.

This process of the 'linguistification of the sacred' is potentially liberating because it releases the 'argumentative force of language' grounded in the capacity of assent or dissent

from any proposition, whether empirical, moral, or aesthetic. ('Linguistification of the sacred' refers to a process in post-traditional societies whereby actions and norms cease to be guided by fear of the sacred but rather are open to rational validity claims. Actions are less governed by unquestionable authorities and are instead open to rational, communicative action, which involves a progressive expansion in critical reflection on norms and practices in everyday life.) In each of these spheres, any attempt to reach an understanding of the truth of a proposition, the sincerity of the speaker, or the appropriateness of the utterance can be disputed. Habermas claims that entering into dialogue about the validity of utterances involves a specific type of discussion (*Diskurs*) oriented toward examining these conditions (Habermas, 1984, p. 28). But here is the nub of the argument. Such practices will be successful only if one assumes equality of access to speech acts and freedom to move from level to level in *Diskurs*, since it is only under such conditions that consensus could be motivated by the force of better argument. This enables Habermas to introduce the 'general symmetry requirement' (also called the 'ideal speech situation'), which states that if a consensus is to be reached guided only by the force of better argument, then whether one recognizes it or not, one routinely assumes certain conditions. That is,

- everyone has an equal chance to deploy, initiate, and perpetuate speech acts,
- utterances are comprehensible,
- their propositional content is true,
- what is said is legitimate and appropriate, and
- it is sincerely spoken.

Habermas's concept of 'ideal speech situation' (also referred to in his work as 'discourse ethics' and 'communicative competence') is used to depict a counterfactual situation in which all participants to communication must have equal opportunity to contribute. They must have the right to assert, defend, or question any factual or normative claim and be motivated solely by the desire to reach a consensus about the truth of statements and the validity of norms. For Habermas, these norms are 'always already' implied in linguistic communication and provide a basis for critique of domination that distorts actual communications in everyday life. Habermas realized, of course, that these conditions of communicative competence are counterfactual and rarely present in actual speech, but it is precisely this that justifies two further claims. The first is that the goal of normal communication is disturbed by power relations, which intrude to prevent questions being raised or validity claims being tested. Second, these constraints on communication are self-defeating since they contradict the underlying assumptions that make dialogue possible at all. From this, it follows that rationality can be measured by the degree of openness or closure in communication. The goals of truth, freedom, and justice are not mere utopian dreams, but are anticipated in ordinary communication, and therefore the goal of emancipation is presupposed in the constitution of the species as linguistic beings (Habermas, 1991, p. 244). If the unspoken authority of all communications can potentially be challenged, then perhaps democratic social relations are already implicit in everyday communications. For this insight to have practical significance, however, it would need to be linked to the formation of emancipatory social movements: feminism, ecology, civil rights, and democratization move ments (Ray, 1993; pp. 57–78).

This analysis and the emancipatory promise it contained, invested in extended democratization of the grammar of everyday, became distinctive of a new turn in critical theory in the later twentieth century. However, the concept of the public sphere in Habermas was grounded in face-to-face interactions and a possibly rather idealized view of the eighteenth century bourgeois 'public.' Prior to the digital revolution and social media, which introduced further dramatic shifts in modes of communication, critics already suggested that Habermas had not given sufficient attention to mass media's obstruction of democratic debate (e.g., Kellner, 1990). Moreover, as Kellner (n.d.) also argues, "the development of new global public spheres with the Internet and new multimedia technology require further development of the concept of the public sphere today and reflection on the emerging importance of new technologies within democracy." But, while Kellner (n.d.) suggests that "The rise of the Internet expands the realm for democratic participation and debate and creates new public spaces for political intervention," others are more pessimistic. For example, Jodi Dean's (2009) concept of 'communicative capitalism' points to a process that subdues deliberative democracy with mass participation in infotainment (Dean, 2009, p. 2). The paradox here is that, far from being de-democratized, the contemporary ideological formation of communicative capitalism "fetishizes speech, opinion, arid participation." It "embeds us in a mindset wherein the number of friends one has on Facebook or MySpace, the number of page-hits one gets on one's blog, and the number of videos featured on one's You Tube channel are the key markers of success." But at the same time meaningful debate, "details such as duration, depth of commitment, corporate and financial influence, access to structures of decision-making, and the narrowing of political struggle to the standards of do-it-yourself entertainment culture become [seen as] the boring preoccupations of baby-boomers stuck in the past" (Dean, 2009, p. 17). In an echo of the pessimism of earlier critical theory she calls this "talk without response" (2009, p. 24).

How Critical Is Critical Theory?

Contemporary critical theory has developed a wide range of debates and projects in the course of which Habermas's has been criticized. For some (Hullot-Kentor, 1989), he has abandoned the earlier critical thrust of Horkheimer and Adorno. For others, he privileges communicative functions of language over others, such as irony or aesthetic expression (Thompson, 1982) and has misunderstood or misused speech act theory (Rasmussen, 1990, p. 37). One of the most frequent criticisms is that if Habermas envisages domination-free dialogue as an attainable state, this is an implausible utopian dream (Jay, 1988, p. 31). If it is not at least potentially an attainable state, then the force of his critique is lost. Similarly, Habermas's emphasis on communication and language is criticized as being idealist and ignoring the importance of material structures (Dux, 1991). Brian Fay suggests that emancipation through rational reflection

encounters limitations imposed by 'embodiment,' since authority is inscribed into conditioned patterns of activity, which cannot readily be subject to rational refection (Fay, 1987, p. 148), thereby signaling the corporal turn in later twentieth and early twenty-first century sociology, with which Habermas has not engaged. Two areas of controversy in particular illustrate the relevance of critical theory to contemporary debates.

Critical Theory and Feminism

Some of the most interesting critiques of Habermas have come from feminist critical theorists, who share his commitment to the explication of power, knowledge, and morality, but differ with him on other issues. A central issue for some is that Habermasian theory stands in the Enlightenment tradition, which many feminists have rejected (Meehan, 1995), while for others he has turned away from the emphasis placed on gender oppression in classical works of critical theory such as the *Dialectic of Enlightenment* (Fischer and Tepe, 2011). Universal pragmatics deals with highly abstract and depersonalized speech rules, which is open to the objection that the materiality of class, gender, and other social divisions remain at the core of society and therefore should be at the center of a critical theory. By contrast, feminist critics have identified discursive forms that represent the experience of embodied female subjects. For example, Nancy Fraser (1985) argues that Habermas fails to examine the gendering of his core concepts such as citizenship, universalism, public sphere, and civil society. The role of citizen is premised on male occupation of the public sphere in which a civil contract among brothers is contrasted with the feminization of the private sphere.

Seyla Benhabib criticizes what she sees as the disembodied transcendental rational ego that is the subject of ideal speech. Drawing on communitarian critics of the 'unencumbered self' (Taylor, MacIntyre), she sees in Habermas's attempt to reconstruct universal morality an autonomous male ego, which universalism privileges as a point of reference. Since subjects are finite and social, contexts of gender and community are central and people are not only generalized others (moral persons with reason) but also concrete others. The negotiation between the 'generalized other' and collective concrete others takes place in a male public sphere from which women disappear (Benhabib, 1992, p. 13). Nonetheless, Benhabib applauds Habermas's shift to communication, which departs from reason as a psychological attribute of consciousness to an intersubjective view of ethics and dialogue.

A similar point is made by Kate Soper, who notes the "all male monastical atmospherics of the Frankfurt School," but sees nonadversarial dialogue as similar to consciousness raising, and his distinction between normatively secured and communicatively achieved dialogue as a means of opening up unquestioned conventions (e.g., family) to explicit discussion. Indeed, there is some anxiety among these critics that the theory risks losing sight of universalism in favor of Romantic particularism. Benhabib asks, "would a moral theory restricted to the standpoint of the concrete other be sexist, racist, culturally relative, and discriminatory?" "No," she replies, "rights must be an essential component of any such theory." The problem here (cf. Soper, 1989) is that 'rights' must involve abstraction from particularity otherwise the grounding for the demand for equal treatment is removed.

In similar vein, Sorial (2011) argues that Habermas's proceduralist model of law, developed in Habermas (1998) can be put to feminist ends in at least two significant ways. First, by presenting an alternative to the liberal and welfare models of laws, the proceduralist model offers feminism a way out of the equality/difference dilemma. This dilemma, which Habermas addresses, arises from the tension between a juridical-liberal model of equality based on equal rights on the one hand and the welfare state model on the other "that developed protective norms in relation to pregnancy and maternity, custody rights, divorce, domestic violence and sexual assault." Both these, however, "merely reinforced existing stereotypes of gender identity" and require women to adapt to patriarchal institutions that they do not in themselves challenge. The "proceduralist model renders this dilemma irrelevant [because] … it proceeds from the fact of sexual difference" and requires that all parties themselves engage in public discussions in which they "articulate their needs, interpret their rights, and take responsibility for the law making process about issues that affect them." Second, Sorial defends Habermas against feminist critics such as Fraser and Dean, claiming that his deliberative model is not inherently masculine or exclusionary. On the contrary, the "requirement that all those affected by a particular norm participate in the debate about that norm not only offers a way of overcoming the equality/difference dilemma … but also necessitates an important institutional shift" in legal institutions themselves by opening up multiple avenues of debate and reconnecting notions of private and public autonomy. Even so, it is not clear to what extent Habermas or Sorial are describing *actual* legal systems or an ideal(ized?) model of a system which, like Hegel's *Rechtsstaat*, did not actually exist.

The Debate over Modernity

In pursuit of his project of salvaging the project of modernity, Habermas confronted what he regarded as another reversion to irrationalism and pessimism in the postmodern theories of the 1980s and 1990s. He appeared to be one of the few social theorists at the time who was willing to defend the tradition of modernity, and was frequently called to do so in debates with theorists like Lyotard, Gadamer, and Foucault. In some ways, the two intellectual movements, critical theory and postmodernism, did share an attention to knowledge and communication media, the fragmentation of culture and identity, and the end of historical narratives. (To be clear, postmodernism was a diffuse intellectual movement in the social sciences, arts, architecture, and literature that rejected universalist Enlightenment 'narratives,' such as reason and progress, in favor of celebration of diversity, fragmentation, and aesthetic irony.) Nonetheless, for critical theory, postmodernism denies the grounds of its own critique and permits celebration of spontaneous power of imagination. For Habermas, that modernity is not exhausted but unfulfilled was

demonstrated by the anticommunist 'rectifying revolutions' (*die nachholende Revolution*) of 1989. These posed anew the core issues of modernity – rights, civil society, market governance, cultural autonomy, and democratic association (Habermas, 1990, 1994, p. 62). Even so, Habermas's (2001) hope that the 1989 revolutions would enable the emergence of a "European civil society; the construction of a European-wide public sphere; and the shaping of a political culture that can be shared by all European citizens resurgence of civil society" in both the east and the west proved too optimistic. In retrospect, many of the utopian hopes that surfaced briefly were disappointed (Ray, 2009; Vogt, 2005), which leaves open the question of what are the conditions for emancipatory critique and practice?

The details of debate over postmodernism subsequently became a little passé since postmodernism as Matthewman and Hoey (2006) suggest "never made it into the 21st century." Nonetheless, the sociological issues that stimulated this debate remain relevant and the question of the possible potentials for emancipatory practice central to the project of critical theory. Moreover, Habermas's robust defense of modernity and enlightenment is as much a challenge to earlier critical theory as to postmodernism. An evaluation of contemporary critical theory should assess its success in identifying emancipatory impulses neglected by earlier theorists. Habermas gestures toward social movements as representing new communicative structures, although he says very little about these in detail. The key issue is whether the theory of communicative action is a plausible reconstruction of the emancipatory potentials inherent in everyday speech. Even if one finds these arguments persuasive, the question remains whether these are cultural conventions or deeper structures constitutive of discourse.

Communication to Recognition?

Habermas has been the dominant theorist of contemporary critical theory for several decades. However, Anderson (2011, p. 46) points out that there is a 'third generation' of critical theorists, among whom Axel Honneth "is the undisputed gravitational center," whose theoretical concerns were shaped by formative experiences of the counterculture of the late 1960s, new social movements, fall of Berlin Wall, and the resurgence of nationalism and globalization. These brought to the fore postmaterial issues of identity, lifestyle, and belonging. Like earlier critical theorists, the new generation draws upon modern Western philosophy, seeks engagement with social science research, and aims to develop a normative critical theory. Honneth's social philosophy places mutual recognition at its core, while retaining a metatheoretical approach to specifying the conditions for social critique. Honneth claims that Habermas is concerned with the social and cognitive restrictions that place limits on unimpeded application of linguistic rules but these do not appear in the moral experiences of subjects (2007, p. 70). He attempts to rectify this by shifting the focus of critical theory from communication to experiences of recognition. This is the key process of social integration while conflict is motivated by *moral* feelings of lack of recognition. Further, Honneth returns to the conceptual lexicon and mood of earlier critical theory, for example, in his reformulation of the concept of reification (Honneth, 2008). In this way, he aims to "close the gap left open by Habermas in his further development of Horkheimer's programme" (2007, p. 72). So, "In place of Habermas's focus on undistorted relations of communication as revealing a standard of justification, Honneth focuses on the progressive overcoming of barriers to full interpersonal recognition, barriers such as legal exclusion and cultural denigration" (Anderson, 2011, p. 54).

Honneth follows Charles Taylor in arguing that recognition is essential to self-realization, although he returns more directly to the Hegelian concept while attempting to explain the normative role of recognition in the formation of social movements. Critical for motivating resistance is the experience of disrespect and denial of recognition. Like Hegel and George Herbert Mead, Honneth identifies three levels of mutuality, namely love, rights, and solidarity (e.g., Honneth, 2007, pp. 129–142).

- Love refers to mutual affirmation and recognition of physical needs, which, especially in the parent–child relationship, is essential to one's ability to achieve both dependence and autonomy. It is located in processes of socialization, family forms, and friendship and it is through the child's emotional attachment to another person that a world of meaningful qualities is disclosed. This is destroyed by physical violence and abuse that will cripple one's trust and ability to form relationships in the world.
- Rights refers to freedom and the absence of arbitrary domination combined with access to the political process and moreover the development of moral responsibility in one's relationships with others. Its context is the institution and application of laws. The denial of rights through legal and social exclusion threatens a person's moral standing and autonomy.
- Solidarity refers to the affirmation and self-esteem that arises from finding one's particularity affirmed within communities. This is essential for developing self-esteem and for how one becomes 'individualized.' For an example of the consequence of refusal of recognition, Honneth cites Orlando Patterson's (1982) concept of 'social death' among Afro-American slaves. The slave was so dependent on the master's authority that he/she became a nonperson in the face of systematic denigration and insult.

For Honneth, negative emotional states of shame, anger, and frustration might make us conscious of an injustice, although these do not automatically disclose relations of disrespect (2007, p. 72). However, they are a "pre-theoretical fact" on the "basis of which a critique of relations of recognition can identify its own theoretical perspective in social reality" (2007, p. 72). So he seems to be claiming that first, these emotional states indicate the potential for naming an injustice based on disrespect and from this the formation of social struggles, and second, that a critical theory is founded on these experiences as well. These expectations of mutual recognition are 'quasi-transcendental interests' of the human race – a claim that locates the critique of their violation in a concept of species being. Like Habermas, Honneth argues that these struggles are not exclusively conflicts over interests, since as

Anderson (1996) points out, the 'grammar' of such struggles is 'moral' in the sense that the feelings of outrage and indignation generated by the rejection of claims to recognition imply normative judgments about the legitimacy of social arrangements. In this way, the normative ideal of a just society is empirically confirmed by historical struggles for recognition.

These views, like Habermas's universal pragmatics, have generated extensive debate and stimulated further theorization of critique and resistance. There has been debate about Honneth's neglect of distributive injustices (e.g., Fraser and Honneth, 2003; Zurn, 2003, 2005). Rogers (2009) argues that focusing on which category – distribution or recognition – is more fundamental misses the complexities of historical political action that presumes they are linked, although this does seem to be the gist of the exchange in Fraser and Honneth (2003). Further, Honneth does regard the subjective experience of injustice (lack of respect) to be a consequence of material inequalities (2007, p. 81ff) but regards the experience of disrespect to be the condition for resistance. However, it has further been argued that shame and humiliation are not necessarily routes to movements for social justice and indeed Thomas Scheff's extensive research on shame and violence puts this claim in considerable doubt (e.g., Scheff, 2000). Shame and humiliation as Sayer (2005) suggests are in some ways the opposite of self-respect and pride and as likely to generate self-contempt as active resistance.

These observations are part of a wider critique that identifies difficulties in his attempt to "fix recognition as a kind of anthropological constant underneath social interaction" (Foster, 2011). O'Mahony (2011) argues that while Honneth's theory provides a rich starting point for sociological analysis it does also have certain weaknesses. First, his action-theoretical orientation does not address institutional and systemic levels of sociological analysis (see also Strydom, 2011). Second, his spheres of recognition are an "uneasy mix of anthropological constants and socio-historically varying standards that inhibit their value for concrete analysis." If they are anthropological, he says, they are 'always already' present in social life but it is then not clear how they vary historically. Third, they are presented as typologically distinct rather than institutionally interdependent in shaping practices across different social spheres. Foster (2011) suggests that Honneth underplays the transformative power of struggle for recognition on the self in the process of working through misrecognition. He further suggests that the Honneth's sociological account of reification is a narrowing of critical theory that could be broadened by an understanding of overcoming misrecognition as a struggle for 'self-awareness of damaged selves.' Recognition is a struggle in which reification and subject formation are entwined and in which recovery of empathetic attunement (the ability to see the other) must be part of a process of self-transformation in which one acknowledges one's own disfigurement. This implies a further return to older psychoanalytical Frankfurt themes entwined with a critique of aesthetic and meaningful senses in capitalism. Finally, here, Rogers (2009) sees in Honneth a paradox of recognition in that psychological integrity and autonomy depend on recognition by the larger political community. This means that subjectivity has to be constructed through the vocabulary of those in power who deny the needs and integrity of the other. He challenges Honneth's account of 'social death' of African-American slaves that Rogers suggests would leave slaves unaware of what to struggle for. This obscures the active process through which oppressed groups reimagine their self-understanding and exhibit resistance, which invokes parallel discursive arenas for developing counterdiscourses. This wide-ranging debate, however, indicates how Honneth's work will become the focus of debates in critical theory in the coming years.

Conclusion

The debates around both Habermas and Honneth pose the question of how to extend the critical theory beyond political philosophy and connect with critique of social conditions and practical engagement. Early critical theory addressed a wide range of social, political, and intellectual issues but central within these was the Marxist critique of the dominance of the commodity form and the problem of consciousness and historical agency. In later critical theory, these problems have been fundamentally recast in that the materiality of the commodity and critique of consciousness has given way to the critique of distorted communication, the program of democratization, and the return to recognition as the basis of sociality. While the critical theory of Habermas, Honneth, and other contemporary representatives has increased in analytical clarity and comprehensive engagement with philosophy and social theory, much of the passion and outrage with which works such as *Dialectic of Enlightenment* were infused has ebbed. Critical theory is rigorous and critical within the confines of scholarly academic work, while attempting to set out the metatheoretical conditions for critique of injustice. However, one will see over the coming years whether the urgency of engaging with early twenty-first century crises of economy, ecology, social integration, democracy, public spaces, and institutions provokes new modalities of theory and praxis. When, as Dean says, one has "talk without response" there is an urgent need to locate the agents of critical and radical social change.

This article is a revision of the previous edition article by H.C. Triandis, volume 5, pp. 2994–2999, © 2001, Elsevier Ltd.

Abstract

In this article, an inclusive approach is taken, covering the study of relationships between behavior and cultural context from three perspectives: the more classical culture-comparative school, cultural psychology, and indigenous psychologies. After a brief review of the history of cross-cultural psychology over the last half century, conceptualizations following the three perspectives are outlined. There are further sections on methodology, empirical research addressing controversial issues, and applied cross-cultural psychology in six areas (acculturation, intercultural relations, intercultural communication and training, work and organizations, health, and national development). A final section gives a brief outlook on the future.

Cross-cultural psychology (CCP) is one of several areas of scholarship that focuses on the relationship between human behavior and cultural context. One definition, formulated by Berry et al. (2011: p. 5), reads:

> Cross-cultural psychology is the study: of similarities and differences in individual psychological functioning in various cultural and ethnocultural groups; of ongoing changes in variables reflecting such functioning; and of the relationships of psychological variables with sociocultural, ecological and biological variables.

With an emphasis on similarities (i.e., cultural invariance) as well as on differences, and the explicit inclusion of ecological and biological variables this is a broad definition. CCP as defined here attempts to encompass three major orientations in the psychological study of behavior–culture relationships: culture-comparative research (the defining and initially dominant approach), cultural psychology, and indigenous psychologies. There is also overlap with entries for various fields of psychology, such as *Developmental Psychology*.

History

Themes found in contemporary thinking have a long history (Jahoda, 1992), but as a subdiscipline of psychology fitting the definition mentioned above CCP started to develop around the mid-twentieth century. In the early 1970s, the field became organized with the *Journal of Cross-Cultural Psychology* (first volume in 1970) and the *International Association for Cross-Cultural Psychology* (first congress in 1972). At that time, perception and cognition were major areas of study. Studies examining the susceptibility for visual illusions of rectangular buildings and streets (carpenteredness of the environment), and of open vs close vistas found variations related to characteristics of the natural environment (Segall et al., 1966). Lack of exposure to pictures (i.e., two-dimensional representations of three-dimensional objects and scenes) was shown to affect the perception of depth (see Deregowski, 1980). Such research demonstrated the relevance of external context and experience on how humans perceive the world.

Research on cognition had moved away from the racist agenda of comparing groups differing in skin color on IQ tests, a prominent, even though hotly debated, activity of (Western) psychology in the first half of the twentieth century. The new research in cognition was based on cognitively simple tasks and, at that time, recent models of information transmission. One example is the distinction between two cognitive styles, called field-independence and field-dependence; their relative prevalence was related to the mode of economic subsistence. Hunter-gatherers tended to be more field-independent (i.e., they identified more easily the target figure in embedded figures tests), than traditional agriculturists (Witkin and Berry, 1975). A second example is research conducted in Africa on recall and categorization in which the importance of local activities and modes of classification was demonstrated (Cole et al., 1971).

An important feature of projects as mentioned was that unschooled traditional farmers and even hunter-gatherers were included in the research design. More than in many recent studies, which tend to be limited to literate samples, it was recognized that a major strength of the cross-cultural method lies in extending the range of cultural variation to the maximum. Much of the early work was summarized in the first edition of the *Handbook of Cross-Cultural Psychology*, edited by Triandis et al. (1980).

After 1980, there have been two notable developments. First, the research agenda became predominantly social–psychological; the self-report questionnaire became the main method of data collection and differences in mean scores between cultures were interpreted in terms of broad cultural dimensions. Four major value dimensions were postulated by Hofstede (1980). One of these was further developed into the individualism–collectivism dimension of which its doyen, Triandis (1995), could rightly claim that it has become the most important syndrome of culture in the literature on CCP.

The second development had to do with a shift in cultural anthropology. In traditional ethnography, a good deal of attention was paid to culture as external context, including kinship relations and economic subsistence (i.e., the 'human-made part of the environment'). The shift was toward a greater focus on culture as internal context ('culture in the minds

of people'). Each separate culture became to be seen as constituting a set of meanings, or even a system of meanings, that should be understood in its own terms. The method of access was through 'thick description' (Geertz, 1973). This reorientation was at the basis of the development of cultural psychology, with the adage that behavior and culture makes each other up (Shweder, 1991). Such ideas were in tune with the concerns of psychologists in non-Western countries who observed that Western instruments, concepts, and theories did not fit the cultural realities of their societies. The rejection of psychological concepts originating in the West has been a major factor in the development of local indigenous psychologies, for example in India (Sinha, 1997).

In the 1990s, most students of behavior and culture belonged to one of two camps: universalism (a theoretical approach that considers basic psychological processes to be shared by all people, and cultures as influencing their manifestation and salience) and relativism (a theoretical approach emphasizing that each culture should be understood in its own terms, rather than being assessed with standards and instruments from elsewhere). In universalism, there is an emphasis on the 'psychic unity' of the human species; cross-cultural differences in manifest behavior should be explained in terms of common underlying psychological mechanisms and processes that are common to all humans. One might say that universalism builds on the assumed primacy of psychological principles. In relativism, such principles are seen as inherently cultural; the primacy of culture is assumed. In the volume on theory and method of the second edition of the *Handbook of Cross-Cultural Psychology* (Berry et al., 1997) the universalism–relativism distinction was the main theme of discussion. Since then, the underlying issues have not been resolved, but especially in applied research they have become less focal. There is now growing recognition that culture-common and culture-specific are the two sides of a single coin.

Theory

This growing respect for theoretical diversity hardly has led to more homogeneity in outlook. Established traditions continue to influence current ideas, and new formulations are adding to the existing variation. The following, often somewhat overlapping, approaches to behavior–culture relationships may be mentioned.

Cultural variables can be defined as *antecedents* of behavior outcomes. Such antecedents need not be deterministic causes; they can also refer to probabilistic and enabling conditions. Important antecedents are affluence (a compound variable covering income, formal education, access to media, etc.) and climate. Such external conditions are supposed to have effects that are internalized and may persist over longer historical periods. However, the resulting cross-cultural differences are interpreted largely in quantitative terms; i.e., differences in manifest behavior are explained in terms of common psychological mechanisms and processes that vary in the salience of their expression across cultures. For example, individualism tends to be conceived of as a broad value dimension with deep historical roots for which higher scores are found in Western societies than elsewhere.

Culture can also be defined as *mediating* between context and individual outcomes. This idea was expressed strongly by Vygotsky (1978) who saw the development of higher mental functions (especially abstract thinking) as a historical process at the level of societies that led to essential cross-cultural inequalities in these functions, especially between literate and illiterate societies. The influence of Vygotsky is explicit in the cultural-historical school of Cole (1996), but with one important modification: cultural context is not postulated to be operating at the level of broadly defined functions, but at the level of specific competences and skills, organized in fields of activity. Various other contemporary approaches, labeled 'sociocultural psychology' in Valsiner and Rosa (2007), such as social representation and action theories, share the basic premise that the culture of a group lies in the understanding and construction of their reality. For example, in action theories the unit of analysis in psychology is taken to be an action, which invariably is embedded in cultural and historical context, and encompasses the intentions of the actor.

The theoretical position of cultural psychology is that *psychological process and behavior content are inseparable*. At an elementary level, there is no disagreement on this; even the unequal pronunciation of the word 'table' in English and in French points to some (minute) differences in the innervations of the speech apparatus between speakers of these two languages. Controversy between schools of thought, or at least a difference in emphasis, emerges at more inclusive levels of conceptualization and explanation. The most important distinction in cultural psychology (overlapping with individualism vs collectivism) is between two modes of construal of the self: the independent and the interdependent mode (Markus and Kitayama, 1991). Methods of neuroscience have been used to find differences in brain functioning that could be characteristic of interdependent self-construal (in East Asian populations), as opposed to independent self-construal (Americans of European descent in the US).

Recent research in cultural psychology tends to postulate less overarching distinctions between cultural populations. For example, culture has been defined as *shared knowledge in a group* (Hong et al., 2000). Such knowledge, which is the outcome of cultural constructions, tends to be domain-specific and even situation-specific. This is shown by the ability of bicultural persons to switch between their two cultural frames when presented with 'primes' (e.g., icons or symbols) representing either of the two cultures. Still, in the *Handbook of Cultural Psychology* (Kitayama and Cohen, 2007) the theoretical position of inseparableness of process and behavior manifestation is largely maintained. At the same time, most empirical research is seeking to follow the experimental method of psychological science with administration of the same tasks across cultures followed by direct comparison of scores. This entails an important shift away from the initial position of cultural psychology, insofar as the use of common methods and concepts only makes sense under assumptions of universalism (see below).

A relativist position, rejecting the use of the same methods and concepts across cultures as (Western) cultural impositions and advocating *culture-specific and culture-appropriate* methods and concepts, continues to be maintained in schools

of indigenous research. Various levels can be distinguished in the evidence for culture-specific functioning. Most frequently reference is made to specific categorizations (e.g., emotion terms, color terms). Broader concepts include pathological syndromes, stages of ontogenetic development, and personality traits that are said to be unique for some culture. At the most general level, there are broad concepts of functioning that tend to be seen as incommensurable across cultures, such as *Ubuntu* in Africa, a form of social orientation that is reminiscent of collectivism (Mkhize, 2004). Evidence for cultural specificity often hinges on the absence of terms corresponding in meaning across languages (see below).

Methodology

Research in CCP has to deal with difficulties in design and measurement that are less central in other fields of psychology. First, experimental designs for causal inference are generally not available. In an ideal experiment, the experimenter has control over both the treatment conditions and the assignment of subjects to these conditions. In CCP, the treatment (i.e., some aspect of living in a certain cultural context) is often vague and imprecise, and participants' assignment to a culture is fixed by virtue of their membership of that culture. This implies that alternative explanations of a finding are difficult to rule out. The onus is on researchers to strengthen their interpretations through replication and checks on alternative explanations, but designs seeking discriminant validation of a preferred explanation continue to be rare in CCP.

Second, any grouping of humans can be referred to as a culture. Ideally, for a comparative study groups are selected that show clear between-group variance and within-group homogeneity for the domain or variable of interest (as for example, with language groups in research on psycholinguistics). The most common grouping in CCP is countries for which such homogeneity obviously is questionable; moreover, the selection of countries is often on and ad hoc basis. In studies, seeking to explore the universality of some theory or relationship between variables a random sample of all cultures would be required. Even larger studies with numerous samples tend to show a bias; as a rule illiterate groups and groups with traditional means of economic subsistence are underrepresented or even totally absent.

The third and most studied methodological issue concerns the question whether or not it makes sense to use a psychological instrument (psychometric test or questionnaire) constructed in one cultural context in some other cultural context. When cultural specificity of behavior is emphasized, virtually any cross-cultural use of instruments is ruled out. On the other hand, researchers with strong universalist views tend to assume that only minor (linguistic) adaptations are needed. The key question is whether psychological data obtained from subjects in different cultures can be considered equivalent (or comparable). For most researchers in CCP, equivalence has become an empirical issue. Over several decades, an increasingly sophisticated set of psychometric approaches has been developed to examine cultural bias (i.e., differences in scores on tests and questionnaires that do not reflect corresponding differences in the trait or concept presumably measured and distort the interpretation of the scores) (Van de Vijver and Leung, 1997). The old dichotomy of a scale being equivalent or inequivalent has been replaced by distinctions between various levels of equivalence that can be examined in a hierarchical sequence of analyses. It may be found, for example, that a cross-cultural data set does not meet psychometric conditions for full-scale equivalence, but only conditions for structural equivalence. Full-scale equivalence implies that a score of a certain value corresponds to the same standing on the trait being assessed, independent of the culture of the respondent. Structural equivalence implies that the same trait is being assessed, as demonstrated, for example, by high correspondence of factor structures. But structural equivalence does not imply that across cultures test takers with the same scores on the instrument will have the same standing on the underlying trait. Evidence of inequivalence, or cultural bias, imposes constraints on cross-cultural comparison of data. It may be noted that bias refers to systematic variance (rather than error variance) and for this reason further analysis is indicated. In such attempts, a combination of qualitative and quantitative approaches, called 'mixed methods' are used to trace the cultural factors in terms of which observed bias can be interpreted (Van de Vijver, 2011).

In a carefully designed culture-comparative study researchers from the various participating cultures should be involved in the design and formulation of items, optimizing translation equivalence. Post hoc analyses after collection of the data will determine whether or not conditions for psychometric equivalence have been met. Large-scale projects for international assessment of quality of education, such as PISA (Programme for International Student Assessment) and TIMMS (Trends in International Mathematics and Science Study), follow this methodology. Such careful design is still exceptional and most studies in CCP are based on existing instruments. Even then, the local experts can help in the translation and adaptation of an instrument to a new target culture. The International Test Commission (2011) has published a set of Guidelines on Adapting Tests that is available at www.intestcom.org/guidelines.

Topics in Empirical Research

The relevance of cultural context for behavior is widely recognized and has led to a large research literature that is impossible to summarize in a brief review. Here three examples will be given of how empirical findings are advancing insights in behavior–culture relationships. The first example reflects on differences between cultures relative to individual differences within cultures. Recent estimates show that the ratio of between-culture variance and within-culture variance (i.e., individual variance) is in the order of 1:10 for self-reports of value types (e.g., Fischer et al., 2010) and 1:8 for dimensions of personality (McCrae et al., 2005). Such estimates of cross-cultural differences are much smaller than would be expected by both experts and the public at large. What are the implications? Of course, there are variables for which there is large heterogeneity between cultures and homogeneity within cultures. This is the case with many conventions (i.e., agreed upon ways how to act in certain situations, what to believe,

'default strategies' in responding, etc.). Also, substantial differences are found in mean ratings of happiness and well-being that are closely associated with the affluence and security, which societies provide for their members (Diener et al., 2010). Together such findings suggest substantial differences in manifest behavior as a function of features in the external context, while psychological mechanisms and processes underlying manifest behavior may be more invariant across cultures than thought in the past.

The second example is the extensive debate on emotions. Words for emotions are found in all cultures, but for some such words in a language there may not be translation equivalent words in some other language (usually English). In cultural anthropology and cultural psychology, it has been argued that such differences point to emotions being cultural constructions that form variable categories. In culture-comparative research emotions tend to be conceived of as biologically rooted discrete categories; here cross-cultural differences are associated with differences in the salience of a certain emotion and with display rules, which proscribe the expression of emotions in various situations (Matsumoto et al., 2008). Older evidence of culture-specificity of emotions hinging on the specificity of emotion terms has been largely refuted. At the same time, a more complex view of emotions has come from componential theory, in which cultural variation can occur in each of several distinguishable features, such as the antecedents events leading to an emotion, bodily reactions, and action tendencies. However, ratings of emotion terms on numerous emotion features across numerous countries and languages have shown limited cultural variation (Fontaine et al., 2013). In turn, a new challenge has emerged from a failure in neuroscience to identify features in the brain characteristic for various emotion categories, which is taken as evidence for constructionist (relativist) views of emotions (Lindquist et al., 2012). All in all, viewpoints appear to be less extreme than a few decades ago, but a unified perspective on culture and emotion is still far off.

Research on relationships between language and thinking, the third example, also can be characterized as gradually having moved from more extreme to more moderate positions both in universalist and in relativist approaches. Much research has been inspired by Whorf's hypothesis that the vocabulary and grammar of a language are determinants of the ideas and thoughts found with the speakers of that language. Such extensive claims by Whorf soon were shown not to stand upto empirical scrutiny and were followed by strong universalist positions, exemplified in the notion of a universal grammar and other invariant features. In turn, for various allegedly invariant properties of languages, exceptions have been found in comparative linguistics, challenging universality (Evans and Levinson, 2009). Research on spatial orientation provides an illustration how careful analysis can point the way to convergence of viewpoints. In Indo-European languages, the location of objects mostly is expressed using an ego-referenced orientation. The statement: 'the chair is to the left side of the table' will change to 'the chair is to the right side of the table' when the speaker moves to the opposite side of the table. In some other language families, there is a preference for an absolute orientation that is independent of the position of the viewer (e.g., 'the chair is to the North of the table,' or 'to the side of the rising sun'). The two frames of orientation have been associated with performance on nonlinguistic tasks and have been taken to support the argument that language has profound effects on cognition. Dasen and Mishra (2010) carried out a series of careful studies in which language was seen as one aspect of a more general web of ecological and sociocultural factors. They found that the use of a particular frame by a respondent depended not only on the dominant orientation mode of the language, but also on features of the task, such as the ease of encoding either with an ego-referenced or an absolute orientation. Their conclusion was that across languages, individuals possess the basic processes needed for either frame.

Each of the three research topics mentioned is an illustration of research in action. Theoretical controversies have not been resolved fully in either of the three, but empirical evidence is slowly shaping insights. Research designs are becoming more sophisticated and there appears to be a shift from claims about major and extensive cross-cultural differences toward more modest interpretations.

Applied Cross-Cultural Research

Most applied research in CCP has a pragmatic agenda; the main question is not how or how much peoples across cultures differ, but how differences can be best addressed and dealt with. There are various fields of applied CCP; in their textbook Berry et al. (2011) present six such areas: acculturation, intercultural relations, intercultural communication and training, work and organizations, health, and national development.

Research on acculturation is rapidly expanding in response to the increase in worldwide migration. The earlier approach to acculturation, which assumed that there would be more or less successful assimilation by migrants to the new culture, has been largely abandoned. It is now recognized that migrants can follow various acculturation strategies. They can focus on the maintenance of what they consider positive in their culture of origin (such as their religion) or on gaining access to the new culture, or on both. There need not be one uniform strategy; there can be variations across domains, such as the public domain and the private domain (with family and friends). In addition, it is recognized that acculturation does not only depend on the migrants themselves, but also on attitudes toward migrants in the larger society and the kinds of settlement policies of a country. Further diversification in research has resulted from differences in theoretical approaches that emphasize stress and coping, cultural learning or social identification (Ward, 2001).

The area of intergroup relations has an international dimension, but most psychological research deals with the relations between groups within culturally plural societies. It is widely held that the best arrangement is multiculturalism, which presupposes an overarching framework of shared values and goals in a society, and mutual tolerance and respect of ethnic and religious groups for each others' cultures and identities. Positive intergroup relations are threatened by psychological mechanisms expressed in concepts such as

stereotypes (cognitive), prejudices (evaluative), and discrimination (overt behavior). The most well-known body of work in this area, aimed at overcoming negative attitudes and discrimination, is based on Allport's contact hypothesis. This hypothesis holds that, under favorable conditions, contact and sharing among members of various groups will promote mutual acceptance. There is extensive evidence supporting Allport's conjecture (Pettigrew and Tropp, 2011) and this has opened up promising perspectives for successful social intervention programs.

Intercultural communication is addressed in a range of disciplines, including linguistics and sociolinguistics, cultural anthropology and communications research. The relevance of this area derives from growing globalization and internationalization. Presence or absence of a shared language is a key factor in communication, but misunderstandings also may follow from subtle factors, such as paralinguistic differences (e.g., pragmatics, such as turn-taking) and mismatches in conventions. In contrast, theories of intercultural communication tend to provide explanations for communication difficulties in terms of dimensions at a high level of abstraction, with individualism–collectivism as the main distinction (Gudykunst, 2005). The main field for intervention is the training of sojourners or expatriates who are preparing to live and work in another culture. There is a host of training programs; one dimension on which they vary is from culture-general (promoting a deeper understanding of both self and cultural others) to culture-specific (information about rules and customs in a society). Unfortunately, for most interventions it is difficult to estimate their effectiveness. Positive reactions of participants form the main evidence for success; few programs have been validated with less impressionistic data.

Cross-cultural research on work and organizations is a large and active area with research ranging from structural characteristics of organizations as they are found in various societies to individual work-related psychological variables. One persistent question is whether across countries the structure of organizations is converging in line with technological demands or whether cultural characteristics prevent such convergence. The largest volume of research is on work-related values across countries, following Hofstede's (1980) formulation of four value dimensions. Despite increasing criticisms this set of dimensions still provides an explanatory framework for a host of differences between countries not only in psychology, but also in other disciplines, such as economics and management research. Another major focus is leadership behavior with topics such as decision making and leadership styles. In the latter domain, the Global Leadership and Organizational Behavioral Effectiveness (GLOBE) project (House et al., 2004) has been a major effort. Studies of work-related individual psychological variables include motivation, job attitudes, organizational commitment, etc. (e.g., Smith et al., 2008).

Applied cross-cultural research on health is the most diversified of the six areas mentioned here. Perhaps more than in other areas the whole range of conceptual and methodological issues is present, including conceptual discussions on the nature of culture, cultural specificity of illnesses and interventions, and (in)equivalence of diagnostic procedures and assessment scales. The area as a whole has been moving from illness as a pathological state to health as a state of well-being with a simultaneous extension from treatment to prevention. Classical topics are the universality of the major mental disorders, schizophrenia and depression, and the place of (non-Western) culture-bound syndromes in Western psychiatric classifications. Another topic, challenging dominant conceptions of psychotherapy, is the study of indigenous approaches to mental healing, with religious principles being emphasized in Muslim countries, the spiritual principle of ancestors in Africa, and retribution and punishment in some Japanese schools of psychotherapy. Prevention research and interventions address severe real-life problems, including malnutrition and transmission of HIV and other sexual diseases. In the more recently developed approach of positive mental health, there are applications on quality-of-life, stress and posttraumatic stress, and on a host of intervention programs seeking to enhance empowerment and well-being of poor and marginalized groups, especially children and women.

CCP and national development is the smallest of the six areas of applied research mentioned here. For a long time, national development was mostly owned by economists and only since it has become evident that financial and technical support are not sufficient to bring about lasting change, has there been more interest in the cultural and psychological side. Still, most of the contributions to the understanding of development come from developmental economists, such as Sen (1999) who views expansion of 'freedoms' (psychologists might say the 'capability of making choices') as the principal route of development. This suggests that intervention programs seeking to enhance empowerment and autonomy might include economic as well as health-related behaviors (Pick and Sirkin, 2010).

Future Outlook

An array of achievements can be listed showing how over the last half century CCP has contributed to insights in the relationships between behavior and culture, but is this reason for satisfaction? *Eminence grise* Gustav Jahoda (2011) recently argued that CCP has become unduly narrow and inward looking. At the same time, he is positive about the potential of CCP, outlining a promising future with theory-driven experimental research, the inclusion of samples from nonliterate societies, and the use of methods that require more direct contacts with participants than the frequently used questionnaire.

A more outward looking CCP will have to incorporate biological and evolutionary thinking. Traditionally, the concept of culture has been closely associated with differences in behavior between groups. Despite theoretical disagreements, outlined earlier, there continues to be broad consensus between researchers of various schools that the interest of research on culture and behavior mainly lies in on how, or how much, cultural populations differ from each other. There is evidence that researchers are biased toward finding and interpreting differences while ignoring evidence of cross-cultural invariance. A further bias is toward interpretations in terms of broad and inclusive concepts. In the history of CCP, it has happened time and again that initially far-reaching

generalizations of cross-cultural differences came to be seen as overgeneralizations in the light of subsequent more precise data (Poortinga, 2003).

The future relevance of CCP may well lie in conceptualizing culture as a common human propensity and understanding cross-cultural variance on psychological variables as variations on common themes. If so, CCP will have to complement its legacy from cultural anthropology with approaches rooted in biology. In that way, the field is well placed to contribute to and counterbalance the biological revolution in psychology. Cross-cultural research brings a much needed range of variation, which can help to put into question too easy invocations of genetic determinants and phylogenetic processes as long as the complexities of environmental influences on gene expression and epigenesis are poorly understood.

This does not mean that CCP should adopt the methods of current biology. Various alternatives are imaginable, one of which would be to follow an integrative approach as envisaged for ethology by Tinbergen (1963) at a time when in that discipline direct observation was the major method. Tinbergen argued that four questions have to be answered in the analysis of any behavior pattern: (1) the mechanisms or causes of the behavior, (2) its evolutionary history, (3) its ontogenetic development, and (4) the function it supposedly serves. There has been debate on the specific questions raised by Tinbergen and in CCP a question about the historical origin of a behavior pattern might have to be added. The point is that in an integrative approach, more questions have to be answered simultaneously and that this urges researchers to consider multiple perspectives.

Whatever vision one may hold on the future of CCP there remains a need to clarify basic issues. In a recent chapter Van de Vijver et al. (2011) formulated four such questions: (1) how 'deep' or profound are cross-cultural differences in psychological functioning; (2) what are the main methodological challenges to the field; (3) how does culture become engrained in human development; and (4) what is the relationship between individual and culture. It is unlikely that agreement will be reached on these questions anytime soon, but that does not rule out further convergence to at least partly shared views.

Abstract

Cross-cultural studies involve persons from different countries and/or ethnic groups. One of the central methodological problems of these studies is bias, the generic term for multiple explanations of cross-cultural differences. Three different types of bias are distinguished, depending on whether the source of interpretation problems derives from the construct, method of the study, or specific items (called construct, method, and item bias or differential item functioning, respectively). Equivalence refers to the implications of bias on score comparability. Linguistic, structural, measurement unit, and full score equivalence are described. Issues in test translation (translation – back-translation, committee designs, decentering) are discussed. Common subject- and culture-sampling schemes in cross-cultural research are mentioned. The article ends with a discussion of issues in combining individual- and country-level characteristics.

Cross-cultural studies involve persons from different countries and/or ethnic groups; a defining characteristic is their comparative nature. Most studies employ quantitative methods of data collection and analysis. Studies of cultural topics that are noncomparative and apply a qualitative methodology can be found in sociology ('cultural studies,' e.g., Barker, 2003), cultural psychology (Greenfield et al., 2003), and cultural anthropology (Angrosino, 2006).

The range of instruments used in comparative studies is very broad, ranging from highly standardized psychological tests, to observation schedules, and free interviews. In many studies existing Western instruments (mental tests, survey questionnaires, personality inventories) are administered either in a new cultural context, or not adapted to enhance their cultural appropriateness (Hambleton et al., 2004).

If two persons from different cultural groups show different scores on a reliable and valid measure of subjective well-being, these score differences may refer to individual differences in subjective well-being. However, the score differences may also arise from differential social desirability or some other response style, inappropriate translation, or inadequacy of the item to measure well-being in both groups. The example illustrates a central problem in cross-cultural research: observed score differences are often susceptible to multiple explanations (Creswell, 2013). When the same instrument has been administered to persons from different ethnic groups, it cannot be taken for granted that the same scores obtained in different cultural groups have the same psychological meaning.

The ambiguity of interpretation is a consequence of the methodological nature of culture as an independent variable. In laboratory studies researchers randomly assign subjects to experimental treatments. The random assignment leads to a firm control of ambient variables; ideally an experimental and control group are matched on all outcome-relevant characteristics (e.g., personality characteristics and socioeconomic status), except for the treatment variable studied (*see* Internal Validity). However, like gender and other intrinsic subject characteristics, culture is not an experimental treatment that can be manipulated. Groups with a different cultural background tend to differ on a variety of outcome-relevant characteristics. These differences may constitute rival explanations of observed cross-cultural differences. Without precautions to rule out these rival explanations, observed cross-cultural differences are open to multiple interpretations. Findings in cross-cultural research are more convincing when rival explanations have been more adequately dealt with.

Bias is the generic name of an important family of rival explanations (*see* Psychometrics). It refers to the common problem in the assessment of nonequivalent groups that scores obtained in different cultural groups are not an adequate reflection of the groups' standing on the construct underlying the instrument. If scores are biased, their psychological meaning is group dependent and group differences in assessment outcome are to be accounted for, at least to some extent, by auxiliary psychological constructs or measurement artifacts. A closely related concept is equivalence which refers to the absence of bias and hence, to similarity of meaning across groups. The two concepts have somewhat different historical roots and areas of application. Whereas bias usually refers to nuisance factors, equivalence has become the generic term for metrical implications of bias.

Bias and equivalence are not inherent properties of an instrument but arise in a group comparison with a particular instrument. Score comparisons of groups that differ in more test-relevant aspects will show a higher susceptibility to bias.

Sources of Bias

There are three bias sources in cross-cultural research. The first is called construct bias; it occurs when the construct measured is not identical across groups. Work on filial piety (psychological characteristics associated with being a good son or daughter) provides a good example (e.g., Yeh and Bredford, 2003). The Western conceptualization is narrower than the Chinese, according to which children are supposed to assume the role of caretaker of their parents when these grow old and become needy. Construct bias precludes the cross-cultural measurement of a construct with the same measure. An

inventory of filial piety based on the Chinese conceptualization will cover aspects unrelated to the concept among Western subjects, while a Western-based inventory will leave an important Chinese aspect uncovered.

An important source of bias, called method bias, can result from sample incomparability, instrument characteristics, tester and interviewer effects, and the method (mode) of administration. Examples are differential stimulus familiarity in mental testing and differential social desirability in personality and survey research. Some sources of method bias can be dealt with by careful preparation of the assessment instrument and its instruction manual (e.g., proper test instruction with a clear specification of what is asked from participants, standardization of administration, and adequate training of testers and interviewers). Yet, it may be impossible to eliminate all outcome-relevant sample characteristics, in particular when the cultural distance of the countries involved is large. There are indications that a country's Gross National Product (per capita) is positively related to its mean score on mental tests and negatively to its mean score on social desirability. Particularly in comparisons of culturally highly dissimilar groups it may be hard or even impossible to eliminate the impact of sources of method bias such as sources familiarity and social desirability.

Finally, bias can be due to anomalies at item level (e.g., poor translations); this is called item bias or differential item functioning. According to a definition that is used widely in psychology, an item is biased if persons with the same standing on the underlying construct (e.g., they are equally intelligent) but coming from different cultural groups, do not have the same average score on the item. The score on the construct usually is derived from the total test score. If a geography test administered to pupils in Poland and Japan, contains the item 'What is the capital of Poland?' Polish pupils can be expected to show higher scores on the item than Japanese students, even when pupils with the same total test score would be compared. The item is biased as it favors one cultural group across all test score levels. Of all bias types, item bias has been the most extensively studied; various psychometric techniques are available to identify item bias (e.g., Obinne and Amali, 2014).

An overview of common ways of addressing bias is given in Table 1.

Types of Equivalence

Elaborating on categorizations in the literature, four different types of equivalence are proposed here. The first type is labeled construct inequivalence. It amounts to comparing apples and oranges (e.g., the comparison of Chinese and Western filial piety, discussed above). Comparisons lack an attribute for comparison, also called tertium comparationis (the third term in the comparison). The second is called structural (or functional) equivalence. An instrument, administered in different cultural groups, shows structural equivalence if it measures the same construct in both groups (e.g., Raven's Standard Progressive Matrices test has been found to measure intelligence in various cultural groups). Exploratory factor analyses followed by target rotations or confirmatory factor analysis of correlation matrices (structural equation modeling) may be applied to examine structural equivalence. Structural equivalence does not presuppose identity of measures across groups. The measures may use different stimuli across groups. If different operationalizations have been chosen, structural equivalence can be examined by comparing nomological networks across groups.

The third type of equivalence is called measurement unit equivalence. Instruments show this type of equivalence if their measurement scales have the same units of measurement and a different origin (such as the Celsius and Kelvin scales in temperature measurement). This type of equivalence assumes interval- or ratio-level scores (with the same measurement units in each culture). It applies when a bias factor with a fairly

Table 1 Strategies for identifying and dealing with bias in cross-cultural research

Type of bias	*Strategies*
Construct bias	Decentering (i.e., simultaneously developing the same instrument in several cultures)
	Convergence approach (i.e., independent within-culture development of instruments and subsequent cross-cultural administration of all instruments)
Construct and/or method bias	Use of informants with expertise in local culture and language
	Use samples of bilingual subjects
	Use of local surveys (e.g., content analyses of free-response questions)
	Nonstandard instrument administration (e.g., 'thinking aloud')
	Cross-cultural comparison of nomological networks (e.g., convergent/discriminant validity studies, monotrait-multimethod studies, connotation of key phrases)
Method bias	Extensive training of administrators (e.g., increasing cultural sensitivity)
	Detailed manual/protocol for administration, scoring, and interpretation
	Detailed instructions (e.g., with sufficient number of examples and/or exercises)
	Use of subject and context variables (e.g., educational background)
	Use of collateral information (e.g., test-taking behavior or test attitudes)
	Assessment of response styles (e.g., social desirability, acquiescence)
	Use of test–retest, training and/or intervention studies
Item bias	Judgmental methods of item bias detection (e.g., linguistic and psychological analysis)
	Psychometric methods of item bias detection (e.g., differential item functioning analysis)
	Error or distracter analysis

Source: Van de Vijver and Tanzer, 1997. European Review of Psychological Assessment (reproduced with the permission of Swets and Zeitlinger).

uniform influence on the items of an instrument affects test scores of different cultural groups in a differential way. Social desirability and stimulus familiarity may exert this influence. Observed group differences in scores are then a mixture of valid cross-cultural differences and measurement artifacts. When the relative contribution of both sources cannot be estimated, the interpretation of group comparisons of mean scores remains ambiguous. Multigroup comparisons of confirmatory factor analytic models have been utilized to examine measurement unit equivalence. This technique, based on comparisons of covariance matrices, can identify bias sources that affect the covariance of items or tests but it cannot differentiate between valid differences in mean scores and bias sources with a uniform influence on all parts of an instrument.

Only in the case of scalar (or full-score) equivalence can direct comparisons be made; it is the only type of equivalence that allows for the conclusion that average scores obtained in two cultures are different. This type of equivalence assumes the same interval or ratio scales across groups. Conclusions about which of the latter two types of equivalence applies are often difficult to draw and controversial. For example, racial differences in intelligence test scores have been interpreted as due to valid differences (scalar equivalence) and as reflecting measurement artifacts (measurement unit equivalence). Scalar equivalence assumes that the role of bias can be safely neglected. The demonstration of scalar equivalence draws on inductive argumentation. Therefore, it is easier to disprove than to prove scalar equivalence. This can be made plausible by measuring presumably relevant sources of bias (such as stimulus familiarity or social desirability) and showing that they cannot statistically explain observed cross-cultural differences in a multiple regression or covariance analysis.

The distinction between the latter two types of equivalence is immaterial when comparing experimental conditions or changes across cultures (e.g., developmental trajectories or training effects). In respect of scales that show measurement unit equivalence, measure changes at the level of full score equivalence.

Structural, measurement unit, and scalar equivalence are hierarchically ordered. The third presupposes the second, which presupposes the first. Moreover, higher levels of equivalence are more difficult to establish. It is easier to demonstrate that an instrument measures the same construct in different cultural groups (structural equivalence) than to demonstrate numerical comparability across cultures (scalar equivalence). On the other hand, higher levels of equivalence allow for more detailed comparisons of scores across cultures. Whereas in the case of structural equivalence, the only factor on which structures and nomological networks can be compared, scalar equivalence allows for more fine-grained analyses of cross-cultural similarities and differences, such as comparisons of mean scores across cultures in *t* tests and analyses of (co)variance.

Linguistic Equivalence

The concept of linguistic equivalence is developed in multilingual studies. Versions of an instrument in different languages show linguistic equivalence if these have the same characteristics that are relevant for the measurement outcome such as meaning, connotations of words and sentences, comprehensibility, and readability. Linguistic equivalence can be jeopardized by various sources, such as incorrect translations, words that are hard or impossible to translate (e.g., the English expression 'distress' does not have an equivalent in many languages), idiomatic expressions and metaphors (e.g., 'feeling blue'), and imprecise quantifiers ('rather often').

Because linguistic equivalence is not always guaranteed by a literal translation, it has become increasingly popular to utilize adaptations. In an adaptation, parts are changed (instead of literally translated) with the aim to improve an instrument's suitability for a target group.

Many studies employ a translation–back-translation procedure (Sperber, 2004). This amounts to a forward translation, followed by an independent back-translation and a comparison of the original and back-translated version, possibly followed by some alterations of the translation. Such a procedure provides a powerful tool to enhance the correspondence of original and translated versions that is independent of the researcher's knowledge of the target language. Yet, it also has some disadvantages. It puts a premium on literal reproduction; this may give rise to a stilted language use in the target version that lacks the readability and natural flow of the original. The problem may be compounded by translators' awareness of their involvement in a translation–back-translation procedure.

A second problem involves translatability. The use of idiom (e.g., the English 'feeling blue') or references to cultural specifics (e.g., references to country-specific public holidays) or other features that cannot be represented adequately in the target language challenges translation–back-translations designs (and indeed all procedures in which existing instruments are translated). During the 1990s there was a growing awareness that translations and adaptations require the combined expertise of social and behavioral scientists (with a competence in the construct studied) and experts in the target language(s) and culture(s). In this so-called committee approach in which the expertise of all relevant disciplines is combined, there is usually no formal accuracy check of the translation. Usage of the committee approach is popular in large international bodies in which texts are translated in many languages like the United Nations and the European Union.

When versions in all languages are developed simultaneously, a procedure called 'decentering' can be used. No single instrument or cultural group is then taken as starting point; individuals from different cultures jointly develop an instrument, thereby reducing the risk of introducing unwanted references to a specific culture.

The judgmental evidence of the designs to enhance linguistic equivalence can be easily combined with statistical approaches to establish equivalence. Reports of multilingual studies often provide a combination of judgmental–linguistic and empirical–statistical evidence to demonstrate the adequacy of an instrument and its translation. There is a tradeoff between the type of translation and the level of equivalence that can be obtained. When most or all questions of an instrument are adapted, structural equivalence is the highest level possible. When most or all items are literally translated, measurement unit and structural equivalence can be obtained. Recent statistical advancements in item response theory and structural equation modeling have made it possible to retain scalar equivalence,

even when not all stimuli are literally translated (provided that all items measure the same underlying construct in each group).

Sampling Cultures and Subjects

Cross-cultural studies can apply three types of schemes to sample cultures. Three types of sampling can be envisaged. The first is probability (or random) sampling. Because of the large cost of a probability sample from all existing cultures, it often amounts to stratified (random) sampling of specific cultures (e.g., Western cultures). The second and most frequently observed type of culture sampling is convenience sampling. The choice of cultures is governed here by availability and cost efficiency: researchers decide to form a research network and all participants collect data in their own country. In the third type, called systematic sampling, the choice of cultures is more based on substantive considerations. A culture is deliberately chosen because of some characteristic, such as in Nisbett and Miyamoto's (2005) study.

In survey research there is a well-developed theory of subject sampling (Scheaffer et al., 2011). In the area of cross-cultural research three types of sampling procedures of individuals are relevant as they represent different ways of dealing with confounding characteristics. The first is probability sampling. It consists of a random drawing from a list of eligible units such as persons or households. Confounding variables are not controlled for. The second type is stratified sampling. A population is stratified (e.g., in levels of schooling or socioeconomic status) and within each stratum a random sample is drawn. The purpose of stratification is the control of confounding variables (e.g., matching on number of years of schooling). The procedure cannot be taken to adequately correct for confounding variables when there is little or no overlap of the cultures (e.g., comparisons of literates and illiterates). The third procedure combines random or stratified sampling with the measurement of control variables. The procedure enables a statistical control of ambient variables (e.g., using an analysis of covariance).

Individual- and Country-Level Studies

The 1990s saw a growing interest in studies combining individual- and country-level data. Two kinds of studies have been reported. In multilevel hierarchical models (Raudenbush and Bryk, 2002), a regression model is used to explain individual variation (e.g., explaining pupils achievement scores on the basis of their intelligence) and class, district, or country variation (e.g., the explanation of the relationship between intelligence and achievement by means of school quality indicators). The second line of research involves the study of the same phenomena at different levels of aggregation (multilevel covariance structure analysis or multilevel factor analysis, Hox, 2002). From a conceptual point of view this line is more complicated, because it is well documented that (dis) aggregation can lead to methodological artifacts such as the ecological fallacy (*see* Ecological Fallacy, Statistics of), the incorrect application of culture-level characteristics to individuals. In each country a proportion of women are pregnant, but obviously, this proportion does not apply to any individual woman. In addition, equivalence issues have to be dealt with (Van de Vijver and Poortinga, 2002). Hofstede's (2001) famous study of values is based on country characteristics; the four dimensions he reported (individualism, power distance, uncertainty avoidance and masculinity–femininity) are characteristics of countries and their applicability to individual behavior cannot be taken for granted and has to be established. Multilevel covariance structure and factor analysis are powerful tools to examine the equivalence of phenomena at different levels of aggregation, answering questions such as the structural (in)equivalence of concepts like individualism–collectivism at individual and country level. For these and various other concepts the structural equivalence at different levels of aggregation is still unresolved.

Abstract

An overview is given of the major methodological issues in cross-cultural research. Different types of bias (at the level of the construct, method, and item) are described; a taxonomy of hierarchically ordered levels of equivalence (comparability) is presented that distinguishes between structural, measurement unit (metric), and score (scalar) equivalence. Sampling of cultures and subjects is discussed. Finally, issues in multilevel modeling are mentioned.

Introduction

Cross-cultural studies involve persons from different countries and/or ethnic groups. One of the central methodological problems of these studies is bias, the generic term for rival explanations of cross-cultural differences. For example, cross-cultural differences found for an inaccurately translated item do not reflect differences in the construct the item is supposed to measure; the cross-cultural comparison is then biased and scores cannot be compared across cultures. Three different types of bias are distinguished, depending on whether the source of interpretation problems derives from the construct, method of the study, or specific items (called construct, method, and item bias or differential item functioning, respectively). Equivalence, the second pivotal concept in cross-cultural research methods, refers to the implications of bias on the comparability of constructs and/or scores. Linguistic, structural, measurement unit, and full-score equivalence are described. Issues in test translation (such as translation, back-translation, and committee designs) are discussed. Common subject- and culture-sampling frames in cross-cultural research are mentioned. The article ends with a discussion of issues in combining individual- and country-level characteristics.

Cross-cultural studies involve persons from different countries and/or ethnic groups; a defining characteristic is their comparative nature. Most studies employ quantitative methods of data collection and analysis, which are also the topic of this article. Studies of cultural topics that are comparative and apply a qualitative methodology have been described by Ragin (1987). Combinations of quantitative and qualitative approaches are slowly emerging in mixed-methods research (Teddlie and Tashakkori, 2009). The range of instruments used in comparative studies is broad – encompassing, among other things, standardized psychological tests, observation schedules, and free interviews. In many studies, existing Western instruments (mental tests, survey questionnaires, and personality inventories) are administered in a new cultural context, either adapted or not to enhance their cultural appropriateness. The methodological framework outlined in this article applies to all these types of instruments. The aim of the framework is to achieve valid inferences about cross-cultural similarities and differences.

The Interpretation of Cross-Cultural Differences

If two persons from different cultural groups show different scores on a reliable and valid measure of subjective well-being, these score differences may refer to individual differences in subjective well-being. However, the score differences may also arise from differential social desirability, acquiescence, extremity scoring, inappropriate translation, or inadequacy of the item to measure well-being in both groups. The example illustrates a central problem in cross-cultural research: Observed score differences are often susceptible to multiple interpretations (Shadish et al., 2002). When the same instrument has been administered to persons from different cultural groups, it cannot be taken for granted that the same scores obtained in different cultural groups have the same psychological meaning.

The ambiguity of interpretation is a consequence of the methodological nature of culture as an independent variable. In laboratory studies, researchers randomly assign subjects to experimental treatments. The random assignment leads to a firm control of ambient variables; ideally, the experimental and control groups are matched on all outcome-relevant characteristics (e.g., personality characteristics and socioeconomic status), except for the treatment variable studied (*see* Internal Validity). However, like gender and other intrinsic subject characteristics, culture is not an experimental treatment that can be manipulated. Groups with a different cultural background tend to differ on a variety of outcome-relevant characteristics. These differences may constitute rival explanations of observed cross-cultural differences. Without precautions to rule out these rival explanations, observed cross-cultural differences are open to multiple interpretations. Findings in cross-cultural research are more convincing when rival explanations have been more adequately dealt with.

Concepts of Bias and Equivalence

Bias is the generic name of an important family of rival explanations. It refers to the common problem in the assessment of nonequivalent groups that scores obtained in different cultural groups are not an adequate reflection of the groups' standing on the construct underlying the instrument.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.44014-6

If scores are biased, their psychological meaning is group dependent and group differences in assessment outcome are to be accounted for, at least to some extent, by auxiliary psychological constructs or measurement artifacts. A closely related concept is equivalence, which refers to the absence of bias and, hence, to similarity of meaning across groups. The two concepts have somewhat different historical roots and areas of application. Whereas bias usually refers to nuisance factors, equivalence has become the generic term for metrical implications of bias.

Bias and equivalence are not intrinsic properties of an instrument but arise in a group comparison with a particular instrument. An instrument that works well in the comparison of two groups may not work well when a third country is involved. The literature on personality is dominated nowadays by the Big Five Model, according to which personality structure can be described by five traits: neuroticism (or its opposite, emotional stability), extraversion, openness, agreeableness, and conscientiousness. There is evidence from many cross-cultural studies that Big Five measures of personality show little bias (McCrae et al., 2005); however, this remarkable absence of bias in applications of studies with Big Five measures does not imply that applications of other measures of personality in the same countries would also be free of bias. Bias is more likely to affect comparisons of groups that differ in more test-relevant aspects.

Sources of Bias

There are three bias sources in cross-cultural research. The first is called construct bias; it occurs when the construct measured is not identical across groups. Ho's (1996) work on filial piety (psychological characteristics associated with being a good son or daughter) provides a good example. The Western conceptualization is narrower than the Chinese, according to which children are supposed to assume the role of caretaker of their parents when the latter grow old and become needy. Construct bias precludes the cross-cultural measurement of a construct with the same measure. An inventory of filial piety based on the Chinese conceptualization will cover aspects unrelated to the concept among Western subjects, while a Western-based inventory will leave important Chinese aspects uncovered.

An important source of bias, called method bias, can result from sample incomparability, instrument characteristics, tester and interviewer effects, and the method (mode) of administration. Examples are differential stimulus familiarity in mental testing and differential social desirability in personality and survey research. Some sources of method bias can be dealt with by careful preparation of the assessment instrument and its instruction manual (e.g., proper test instruction with a clear specification of what is asked from participants, standardization of administration, and adequate training of testers and interviewers). Yet, in practice it is often impossible to eliminate all outcome-relevant sample characteristics, particularly when the cultural distance of the countries involved is large. There are indications that a country's Gross National Product (per capita) is positively related to its mean score on mental tests (Brouwers et al., 2009) and negatively related to its mean score on acquiescence and social desirability (Van Hemert et al., 2002). Particularly in comparisons of culturally highly dissimilar groups, it may be hard or even impossible to eliminate the impact of sources of method bias such as source familiarity and social desirability.

Finally, bias can be due to anomalies at the item level (e.g., poor translations); this is called item bias or differential item functioning. According to a widely used definition, an item is biased if persons who have the same standing on the underlying construct (e.g., they are equally intelligent) but come from different cultural groups do not have the same expected score on the item. The expected item score is usually derived from the total test score. If a geography test administered to pupils in Poland and Japan contains the item 'What is the capital of Poland?' the test would be said to be biased in favor of Polish students, who can be expected to show higher scores on the item than Japanese students, even when pupils with the same total test score are compared. The item is biased as it favors one cultural group across all test score levels. Of all bias types, item bias has been the most extensively studied; various psychometric techniques are available to identify item bias (e.g., Osterlind and Everson, 2009). An overview of common ways of addressing bias is given in Table 1.

Types of Equivalence

Elaborating on categorizations in the literature, four different types of equivalence are proposed here (Matsumoto and Van de Vijver, 2011; Van de Vijver and Leung, 1997). The first type is labeled construct inequivalence. It amounts to comparing apples and oranges (e.g., the comparison of Chinese and Western filial piety, discussed in this article). Comparisons lack an attribute for comparison, also called *tertium comparationis* (the third term in the comparison). Such views can be found among authors who argue that human experiences are made up by and therefore bound to their cultural context; depression is incomparable across cultures as it entails experiences that are tied to a specific cultural and historical context. Proponents of such a view, according to whom psychological phenomena are fundamentally incomparable across cultures, would argue in favor of construct inequivalence. The second is called structural (or functional) equivalence. An instrument administered in different cultural groups shows structural equivalence if it measures the same construct in each group (e.g., Raven's Standard Progressive Matrices test has been found to measure intelligence in various cultural groups). Exploratory factor analyses followed by target rotations or confirmatory factor analysis of covariance matrices (structural equation modeling) may be applied to examine structural equivalence. Structural equivalence does not presuppose identity of measures across groups. The measures may use different stimuli across groups. If different operationalizations have been chosen, structural equivalence can be examined by comparing nomological networks across groups.

The third type of equivalence is called measurement unit or metric equivalence. Instruments show this type of equivalence if their measurement scales have the same units of measurement but a different origin (such as the Celsius and Kelvin scales in temperature measurement). This type of equivalence assumes interval- or ratio-level scores (with the same

Table 1 Strategies for identifying and dealing with bias in cross-cultural research

Type of bias	*Strategies*
Construct bias	Simultaneous development of an instrument in several cultures
Construct and/or method bias	Use of informants with expertise in local culture and language
	Use of samples of bilingual subjects
	Use of local surveys (e.g., content analyses of free-response questions)
	Cognitive interviewing
	Cross-cultural comparison of nomological networks
Method bias	Extensive training of administrators (e.g., increasing cultural sensitivity)
	Detailed manual or protocol for administration, scoring, and interpretation
	Detailed instructions (e.g., with a sufficient number of examples and/or exercises)
	Use of subject and context variables (e.g., educational background) that can be used for statistical control
	Use of collateral information (e.g., test-taking behavior or test attitudes)
	Assessment of response styles (e.g., social desirability or acquiescence)
	Use of test–retest, training, and/or intervention studies
Item bias (differential item functioning)	Judgmental methods
	Psychometric methods

Adapted from Van de Vijver, F.J.R., Tanzer, N.K., 2004. Bias and equivalence in cross-cultural assessment: an overview. European Review of Applied Psychology 54, 119–135.

measurement units in each culture). It applies when a bias factor with a fairly uniform influence on the items of an instrument affects test scores of different cultural groups in a differential way. Social desirability and stimulus familiarity may exert this influence. Observed group differences in scores are then a mixture of valid cross-cultural differences and measurement artifacts. When the relative contribution of both sources cannot be estimated, the interpretation of group comparisons of mean scores remains ambiguous. Multigroup comparisons of confirmatory factor analytic models have been utilized to examine measurement unit equivalence (Byrne, 2009). This technique, based on comparisons of covariance matrices, can identify bias sources that affect the covariance of items or tests, but it cannot differentiate between valid differences in mean scores and bias sources with a fairly uniform influence on all parts of an instrument (examples of such influences would be response styles like acquiescence or extremity scoring). Only in the case of scalar (or full-score) equivalence can direct comparisons be made; it is the only type of equivalence that allows for the conclusion that average scores obtained in two cultures are different. This type of equivalence assumes the same interval or ratio scales across groups. Conclusions about which of the latter two types of equivalence applies are often difficult to draw and subject to interpretation differences and controversy. For example, racial differences in intelligence test scores have been interpreted as due to valid differences (scalar equivalence) and as reflecting measurement artifacts (measurement unit equivalence). Scalar equivalence assumes that the role of bias can be safely neglected. The demonstration of scalar equivalence draws on inductive argumentation. Therefore, it is easier to disprove than to prove scalar equivalence. This can be made plausible by measuring presumably relevant sources of bias (such as stimulus familiarity or social desirability) and showing that they cannot statistically explain observed cross-cultural differences in a multiple regression or covariance analysis. The distinction between the latter two types of equivalence is immaterial when comparing experimental conditions or changes across cultures (e.g., developmental trajectories or training effects).

Structural, measurement unit, and scalar equivalence are hierarchically ordered. The third presupposes the second, which presupposes the first. Moreover, higher levels of equivalence are more difficult to establish. It is easier to demonstrate that an instrument measures the same construct in different cultural groups (structural equivalence) than to demonstrate numerical comparability across cultures (scalar equivalence). However, higher levels of equivalence allow for more detailed comparisons of scores (and, hence, constructs) across cultures. Whereas in the case of structural equivalence, only factor structures and nomological networks can be compared, scalar equivalence allows for more fine-grained analyses of cross-cultural similarities and differences, such as comparisons of mean scores across cultures in *t* tests and analyses of (co) variance.

In the last 10 years, it has become increasingly popular to apply structural equation modeling to investigate equivalence in so-called multigroup comparisons (Byrne, 2009). This advanced type of statistical modeling can be used to test different levels of equivalence, ranging from structural equivalence to scalar equivalence. The former is taken to be supported if factor loadings are identical across cultures. The latter is usually operationalized as identical intercepts in regression lines that link items to their construct. In all major software packages of structural equation modeling, multigroup options are available. On the one hand, these techniques are rigorous, have a rather firm statistical basis, and allow for a detailed test between different levels of equivalence; on the other hand, in these procedures it is easy to overlook sources of bias that were not measured. For example, if an instrument to assess extraversion is administered in different cultures, a multigroup comparison may provide a detailed view on sources of incomparability in items, but such an analysis will not reveal that important indicators of extraversion (such as specific manifestations of extraversion in that culture) may have been left out. An item about being the life of the party may be found to perform poorly in a particular culture, but such an analysis will not suggest alternatives, so multigroup modeling does not replace the value of a pilot test or focus groups to identify culture-relevant markers of constructs.

Linguistic Equivalence

The concept of linguistic equivalence is relevant in multilingual studies. Versions of an instrument in different languages show linguistic equivalence if these have the same characteristics that are relevant for the measurement outcome such as meaning, connotations of words and sentences, comprehensibility, and readability. Linguistic equivalence can be jeopardized by various sources, such as incorrect translations, words that are hard or impossible to translate (e.g., the English 'distress' does not have an equivalent in many languages), idiomatic expressions and metaphors (e.g., 'feeling blue'), and imprecise quantifiers ('rather often').

Because linguistic equivalence is not always guaranteed by a close translation, it has become increasingly popular to utilize adaptations. In an adaptation, parts are changed (instead of literally translated) with the aim to improve an instrument's suitability for a target group. Many studies employ a translation–back-translation procedure (Brislin, 1986). This amounts to a translation, followed by an independent back-translation and a comparison of the original and back-translated version, possibly followed by some alterations of the translation. Such a procedure provides a powerful tool to enhance the correspondence of original and translated versions that is independent of the researcher's knowledge of the target language. Yet, it also has some disadvantages. It puts a premium on literal reproduction; this may give rise to a stilted language use in the target version that lacks the readability and natural flow of the original. The problem may be compounded by translators' awareness of their involvement in a translation–back-translation procedure. Translators who know that the criterion for judging the quality of translation will be the equality of original and back-translated versions may focus more on compliance with this criterion and less on the quality of the text in the target language.

A second problem involves translatability. The use of idioms (e.g., the English 'feeling blue'), references to cultural specifics (e.g., references to country-specific public holidays), or other features that cannot be represented adequately in the target language challenges translation and back-translation designs (and, indeed, all procedures in which existing instruments are translated).

During the 1990s, there was a growing awareness that translations and adaptations require the combined expertise of social and behavioral scientists (with a competence in the construct studied) and experts in the target language(s) and culture(s). This awareness led to the use of new translation designs. An example is the so-called committee approach in which the expertise of all relevant disciplines is combined and in which there is usually no formal accuracy check of the translation. Combining different types of expertise that may be needed for a translation, such as linguistic and technical knowledge in the translation of technical documents, is relatively easy in a committee approach. Another approach is to commission multiple, independent translations of an instrument to a target language so that multiple versions can be compared and, if differences are found, the best can be chosen. An important characteristic of current large-scale cross-cultural studies is their awareness of the need for thorough quality checks of the translations, as poor translations can challenge the validity of cross-cultural studies. All kinds of procedures have been proposed to check the accuracy of translations. An example is Harkness's (2003) five-step TRAPD procedure, an acronym for translation, review, adjudication, pretesting, and documentation. These quality checks usually go much beyond verifying the accuracy of the translation by linguists and entail the administration of the new version in the target group and an evaluation of the psychometric properties of the instrument to ensure that the construct as measured is the construct as intended.

The judgmental evidence of the designs to enhance linguistic equivalence can be easily combined with statistical approaches to establish equivalence. Reports of multilingual studies often provide a combination of judgmental–linguistic and empirical–statistical evidence to demonstrate the adequacy of an instrument and its translation. There is a trade-off between the type of translation and the level of equivalence that can be obtained. When most or all questions of an instrument are adapted, structural equivalence is the highest level possible. When most or all items are literally translated, measurement unit and structural equivalence can be obtained. Recent statistical advancements in item response theory and structural equation modeling have made it possible to retain scalar equivalence, even when not all stimuli are literally translated (provided that all items measure the same underlying construct in each group). It is one of the achievements of recent decades in cross-cultural research methods that previously unlinked concepts (equivalence in a quantitative framework and in a linguistic framework) are now more linked in both the design and analysis stages of cross-cultural studies.

Sampling Cultures and Subjects

Cross-cultural studies can apply three types of schemes to sample cultures. Three types of sampling can be envisaged. The first is probability (or random) sampling. Because of the large cost of a probability sample from all existing cultures, it often amounts to stratified (random) sampling of specific cultures (e.g., Western cultures). The second and most frequently observed type of culture sampling is convenience sampling. The choice of cultures is governed here by availability and cost efficiency: researchers decide to form a research network, and all participants collect data in their own country. In the third type, called systematic sampling, the choice of cultures is more based on substantive considerations. A culture is deliberately chosen because of some characteristic.

In survey research, there is a well-developed theory of subject sampling (Kish, 1965). In the area of cross-cultural research, three types of sampling procedures of individuals are relevant as they represent different ways of dealing with confounding characteristics. The first is probability sampling. It consists of a random drawing from a list of eligible units such as persons or households. Confounding variables are not controlled for. The second type is stratified sampling. A population is stratified (e.g., in levels of schooling or socioeconomic status), and within each stratum a random sample is drawn. The purpose of stratification is the control of confounding variables (e.g., matching on number of years of schooling). The procedure cannot be taken to adequately

correct for confounding variables when there is little or no overlap of the cultures (e.g., comparisons of literates and illiterates). The third procedure combines random or stratified sampling with the measurement of control variables. The procedure enables a statistical control of ambient variables (e.g., using an analysis of covariance).

Individual- and Country-Level Studies

The 1990s saw a growing interest in studies combining individual- and country-level data. Two kinds of studies have been reported. In multilevel hierarchical models (Snijders and Bosker, 2011), a regression model is used to explain individual variation (e.g., explaining pupils' achievement scores on the basis of their intelligence) and class, district, or country variation (e.g., the explanation of the relationship between intelligence and achievement by means of school quality indicators). The second line of research involves the study of the same phenomena at different levels of aggregation (multilevel covariance structure analysis or multilevel factor analysis; Hox, 2010). From a conceptual point of view, this line is more complicated because it is well documented that (dis)aggregation can lead to methodological artifacts such as the ecological fallacy (*see* Ecological Fallacy, Statistics of), which is the incorrect application of culture-level characteristics to individuals. As an example, in each country a proportion of women is pregnant, but obviously, this proportion does not apply to any individual woman. In addition, equivalence issues have to be dealt with. Hofstede's (2001) famous study of values is based on country characteristics; the four dimensions he reported (individualism, power distance, uncertainty reduction, and masculinity–femininity) are characteristics of countries, and their applicability to individual behavior cannot be taken for granted and has to be established. Multilevel covariance structure and factor analysis are powerful tools to examine the equivalence of phenomena at different levels of aggregation, answering questions like the structural (in)equivalence of concepts like individualism–collectivism at individual and country levels. For these and various other concepts, the structural equivalence at different levels of aggregation is still unresolved.

This article is a revision of the previous edition article by G. Trommsdorff, P. Dasen, volume 5, pp. 3003–3007, © 2001, Elsevier Ltd.

Abstract

This article summarizes the contemporary research on cross-cultural study of education. Specifically, a summary of large-scale international assessments of academic achievement and teaching is presented, along with a cultural analysis of how home, school, and individual factors relate to academic performance.

An analysis of cross-cultural studies of education first necessitates an operational definition of culture. Culture is generally defined as a universal way of life, one that consists of people collectively using all resources in their environment to achieve; is learned, shared, and regulated by political, legal, and social systems; is socially transmitted; is represented by both external (observable behaviors) and internal (inferred traits) aspects of an individual; and is an abstraction of people's knowledge and beliefs about themselves, other people, and the world (Zusho and Clayton, 2011). In cross-cultural research, culture is often operationalized in terms of global categories such as nation of origin, social class, and race/ethnicity. Increasingly, however, researchers are recognizing that defining culture entirely in terms of these global categories promotes a limited, static approach to culture (Zusho and Clayton, 2011). Accordingly, more and more emphasis is being placed on capturing the heterogeneity within groups in cross-cultural research.

When broadly conceived, education can be equated with the interwoven processes of enculturation and socialization – as the cultural transmission of knowledge, skills, customs, and values from one generation to another. In the contemporary world, education is most often associated with schooling, both formal and informal. Cross-cultural studies of education therefore concerns the comparative study of the similarities and differences in schooling, including achievement, instruction, and beliefs about learning and instruction. The current focus within this area of research is an examination of how schooling is impacted and changed by sociocultural, ecological, and to a lesser extent, biological forces.

In general, cross-cultural studies of education are guided by three main goals (Berry et al., 2002). The first goal, the 'transport and test' function, concerns the testing of the generalizability of mainstream (typically Western, i.e., American, European, and Australian) theories to other cultures, for example, to test theories of motivation and learning across cultures. The second goal – the 'exploration and discovery' goal – in turn, entails exploring other cultures to discover variations absent in mainstream theories. An example of the second goal would be to explore other cultures to see if there are culture-specific motivations for learning. The second goal usually results from failure to find similarities across cultures as reflected in the transport and test function. Thus, the exploration and discovery goal largely aims to understand why theories and hypotheses fail to generalize in a particular culture by examining its ecological, historical, and cultural contexts. Finally, the third goal concerns the development of universal theories that is acceptable across cultural contexts via integration of the first two goals, for instance the development of universal theory of motivation.

International Assessments of Achievement

Although comparative studies of education can be traced back to the nineteenth century (Rust et al., 2009), cross-cultural studies of education did not begin to take center stage until the 1960s when the International Association for the Evaluation of Educational Achievement (IEA) conducted its first large-scale international assessment of educational achievement. Building on a previous pilot study, the IEA launched the First International Mathematics Study in 1964, which was subsequently followed up by the First International Science Study and the Study of Reading Comprehension in 1968. Since then, the IEA has commissioned numerous international assessments, including the Second and Third International Mathematics and Science Studies (SIMS, SISS, TIMSS). Current IEA studies of student achievement include assessments of computer and information literacy (International Computer and Information Literacy Study, 2013), mathematics and science (TIMSS, 2011, now known as Trends in International Mathematics and Science Study), reading literacy (Progress in International Reading Literacy Study (PIRLS), 2011), and civic and citizenship education (International Civic and Citizenship Education Study, 2009).

The Organisation for Economic Co-operation and Development (OECD) is also responsible for a number of international comparisons of education, including the Programme of International Student Achievement (PISA) and the Programme for the International Assessment of Adult Competencies (PIAAC). Since 2000, the OECD has administered PISA every 3 years with the intention of measuring how well member nations educate their youth in the areas of mathematics, reading, and science. Specifically, PISA assesses to what extent students can apply what they learned in school to real-life situations. PIAAC, in turn, is designed to assess the life skills of adults (aged 16–65 years), particularly those related to success in a twenty-first-century global economy.

Overall, these large-scale international assessments appear to be motivated by several interrelated goals. First is the goal to broaden knowledge of educational systems around the world

and to discern general educational trends across participating nations. A second, more pragmatic, goal is to identify characteristics of 'successful' educational systems (as indicated by consistent, superior performance on standardized educational assessments irrespective of socioeconomic background), so that it can be used as a model for others. It is worth mentioning that these studies generally assume that it is possible to reliably measure academic achievement across cultural contexts since it is possible to establish, at least partially, that students in different countries respond to achievement items in similar ways (i.e., metric invariance, see Steenkamp and Baumgartner, 1998). Indeed, items on TIMSS assessments are routinely scrutinized for whether or not they are biased toward or against individual countries (Martin et al., 2004). Another commonly held assumption is that rankings of nations on assessments will change over time, and can be used to encourage participating countries to improve their own teaching and student performance (OECD, 2010c).

Across the international assessments, several conclusions can be drawn. First, students from East Asian countries (e.g., Korea, Shanghai-China, Hong Kong, and Singapore) typically achieve the highest scores on tests of mathematics and science (Martin et al., 2008; Mullis et al., 2008; OECD, 2010c). Second, girls, on average, score higher than boys in reading (Mullis et al., 2007; OECD, 2010c), whereas males outperform females in mathematics by the time they are 15 years of age (OECD, 2010c). Third, although achievement rankings may not be tied to a nation's overall wealth (OECD, 2010c), there appears to be a positive relationship between students' socioeconomic background and achievement scores. For example, students who attend schools with a higher proportion of economically disadvantaged students generally do more poorly than students who attend schools with a lower proportion of students who come from economically disadvantaged backgrounds (Martin et al., 2008; Mullis et al., 2008; OECD, 2010c). Finally, there is a general trend toward improvement in achievement scores among participating nations over time (Martin et al., 2008; Mullis et al., 2008; OECD, 2010c). Specifically, there appears to be a narrowing of the gap in achievement scores among students who score at the top and bottom (OECD, 2010c).

Support for Learning: Schools and Teachers

One major focus of cross-cultural studies of education is schools and teachers. Specifically, these studies generally explore how and to what extent do schools and teachers provide all students the opportunity to learn. To this end, studies have been conducted on various aspects of schooling and instruction, including curricular content, quality of instruction, as well as other teacher-related variables (e.g., teacher beliefs and preparation of teachers).

In general, studies of instructional time and curricular content reveal more similarities than differences across countries. On average, studies report that teachers spend approximately 23–24 h a week in classroom instruction (Mullis et al., 2008; OECD, 2004). Most of the instructional time at the younger grades is, not surprisingly, focused on reading and language instruction (Mullis et al., 2007), followed by mathematics and then science (Martin et al., 2008; Mullis et al., 2008). In addition, most countries report teaching the topics presented on international assessments, indicating that there are commonalities in curriculum content across participating nations (Martin et al., 2008; Mullis et al., 2008). For science, however, there appears to be one major difference; countries vary in whether they teach science as a single integrated subject, or as separate subjects. As for specific instructional practices, teachers in most countries report spending the most instructional time on structuring practices, such as stating learning goals, summarizing and reviewing previous lessons and homework, and checking for student understanding (OECD, 2009).

Although the content of curriculum does not appear to vary considerably across countries, there is some emerging evidence to suggest that cultural differences may exist in curricular *coherence* – that is the extent to which the sequence of topics presented in the curriculum is logical, progressive, and corresponds to the natural structure of the discipline from which it is drawn (Schmidt et al., 2005). Schmidt et al. (2005) argue that countries that perform at the top of the TIMSS comparisons generally have mathematics and science curricula that are coherent and promote conceptual understanding. They further argue that the US math and science curricula are generally organized in an ad hoc fashion, and attempt to cover almost every topic at every grade, resulting in a 'mile-wide inch-deep curriculum.'

There is, too, limited evidence that the quality of instruction may vary culturally (Tatto et al., 2012). For example, the results of the TIMSS video case studies (Stigler et al., 1999; Hiebert et al., 2003) suggest that the mathematics instruction in certain countries may be of higher quality than others. The 1999 study, which examined eighth-grade mathematics lessons from six countries (Australia, Czech Republic, Hong Kong Special Administrative Region, the Netherlands, Switzerland, and the United States), rated the quality of instruction to be highest in Hong Kong and lowest in the United States. The OECD studies further suggest that disciplinary climate, as measured by time on task, frequency of classroom distractions, teacher control, and other indices of classroom management, is an important predictor of achievement test scores (OECD, 2010a).

Recent studies such as the OECD's Teaching and Learning International Survey (TALIS) (OECD, 2009) and the IEA's Teacher Education and Development Study in Mathematics (TEDS-M) focus on the working conditions and preparation of teachers, respectively. TALIS had four major foci: teachers' professional development (PD); teachers' teaching practices, beliefs, and attitudes; teacher appraisal and feedback; and school leadership. Overall, TALIS findings indicate that most teachers are satisfied with their jobs and feel that they make a considerable impact on their students. However, despite varying levels in the intensity and level of participation in PD, most teachers, on average, report that their PD needs are generally not being met; for example, more than half of the teachers surveyed reported wanting more PD that they had received, specifically related to teaching students with special needs (OECD, 2009). TALIS results also indicate that with the exception of Italy, teachers, particularly those in Austria, Australia, Belgium, Denmark, Estonia, and Iceland, generally perceive that their role is more to support students'

construction of knowledge rather than to simply present facts and giving students opportunities to practice.

The results of TEDS-M, in turn, indicate that there is variability in how countries prepare their teachers (Tatto et al., 2012). First, teacher education systems vary in terms of teacher selectivity and status; for example, more stringent admissions criteria are observed in countries with an oversupply of potential candidates (e.g., Chinese Taipei). The general background of teacher candidates, therefore, varies across nations – for example, the proportion of teacher candidates who possess advanced degrees in mathematics and consider themselves to be mathematics specialists are much higher in countries where teaching is a more popular profession. Teacher education systems also differ in terms of the length of program, the amount of class time allocated to mathematics and mathematics pedagogy, as well as field experiences. The results of TEDS-M also provide initial evidence that variability within and across teacher education programs are partly attributable to differences in mathematics content knowledge, teacher beliefs, and general opportunities to learn (Tatto et al., 2012).

In short, the collective studies on teaching and schooling suggest that a combination of factors related to teaching and schooling are likely to be related to higher student performance. The OECD (2010b) characterizes 'successful' school systems as those who provide *all* students equal opportunities to learn; in other words, school systems with limited tracking where economically advantaged and disadvantaged students attend the same schools, and schools with low transfer rates related to poor academic performance or behaviors. Successful school systems also generally provide greater autonomy and resources to individual schools.

Support for Learning: Home and Family

Research indicates that it is not only teachers and schools that have an effect on students' performance. Indeed, mounting evidence suggests that students' home background may make an equal, if not more, significant impact on students' learning outcomes (OECD, 2003). Thus, increasing attention is being paid to investigating how various home factors relate to learning. For example, the results of the TIMSS studies largely indicate that students who achieve at the top of international comparisons speak the language of the test at home, have parents with relatively higher levels of education, and also have access to computers and books at home (Martin et al., 2008; Mullis et al., 2008).

Perhaps the greatest evidence of the impact of home factors on achievement comes from studies of reading. For example, PISA data consistently demonstrate a positive relationship between socioeconomic status and literacy performance (OECD, 2003). It appears that the impact of advantaged family background is present in every country, but particularly pronounced in Latin American countries such as Peru and Argentina. Results of PIRLS 2006 continue to demonstrate a positive relationship between students' fourth-grade reading achievement and the extent to which parents engage their children in early literacy activities (e.g., reading books, telling stores, singing songs, and playing with alphabet toys and other word games) before starting school (Mullis et al., 2007). Students who come from homes with more than 100 books were also found to achieve, on average, close to 1 standard deviation higher on the PIRLS reading assessment than children who come from homes with 10 or fewer books. Correspondingly, the average reading achievement was highest among students who had parents who were frequent readers and who had favorable attitudes toward reading (Mullis et al., 2007).

Taken together, these findings demonstrate that the home is an important context for socialization and that family characteristics such as wealth, parental education, and access to and support of early literacy activities are a major source of disparity in students' reading achievement.

Support for Learning: Individual Attitudes and Beliefs about Learning

Apart from school- and home-related contextual factors, there is ample evidence that students' personal attitudes and beliefs about learning also play an important role in explaining learning outcomes. To date, most of this research has focused on examining cross-cultural differences in students' motivational beliefs, as well as learning strategies (Zusho and Clayton, 2011; McInerney, 2011). Briefly, motivational beliefs are usually composed of students' interest and enjoyment in school-related matters, learning goals, beliefs about identity (self-concept) and ability (self-efficacy), and attributions for success and failure, specifically the role of effort and ability. Similarly students' learning strategies are usually characterized as being deep or surface level (Biggs, 1987). Deeper processing learning strategies promote conceptual understanding and typically involve the use of elaborative cognitive and metacognitive strategies such as making connections between new material and prior knowledge, or regulating and monitoring one's understanding of material during study (Pintrich and DeGroot, 1990; Zimmerman and Martinez-Pons, 1986; Zimmerman, 1990). In contrast, surface-level learning strategies generally focus more on task completion, and rote memorization.

Based on this emerging area of study, certain generalizations can be made about the relationship of motivational beliefs, learning strategies, and academic performance across cultures. First, research on both Eastern and Western students suggests that students who display more adaptive motivational profiles (i.e., higher levels of intrinsic motivation, focus on goals focused on learning and understanding) generally employ more deeper processing learning strategies than those students who display more maladaptive profiles (Lepper et al., 2005; Schmuck et al., 2000). Second, research confirms that deep learning strategies are positively related to academic achievement across cultures (Watkins, 2000, 2001). Moreover, results from OECD (2010d) found that students who enjoy reading, are highly engaged in the learning process, monitor and evaluate their learning, and are aware of what strategies are effective for learning tend to perform better in the PISA reading assessment.

Such generalizations notwithstanding, studies on Eastern and Western countries have also identified cross-cultural

differences in the relations of certain motivational constructs and learning outcomes. For example, in Western countries, empirical findings typically find student self-perceptions (e.g., self-concept, self-efficacy) to be a strong predictor of individuals' effort, cognitive engagement, academic achievement, and subjective well-being (Bandura, 1997; Linnenbrink and Pintrich, 2003). Paradoxically, however, it is typically found that in Eastern countries, lower levels of self-concept or self-efficacy are oftentimes a better predictor of academic performance (Klassen, 2004a,b; Leung, 2001; Mau, 2000).

Similarly, differences have been noted in the attributional styles of Eastern and Western students. For example, a number of studies report Eastern students to attribute academic success more to effort than to ability, in comparison to Western students who make more ability-based attributions for success (e.g., Ho et al., 1999; Holloway, 1988). It is important to note, however, that it may be somewhat premature to make cross-cultural generalizations about attributional style. For example, Bempechat and colleagues caution that Asian students do not always emphasize effort over ability, and that ability attributions may play a more significant role in explaining Asian and Asian-American students' academic performance (Bempechat and Drago-Severson, 1999; Choi et al., 1994). Western students, too, appear to emphasize effort over ability at times; British children in particular have been noted to attribute success in school to effort rather than ability (Gipps and Tunstall, 1998; Lightbody et al., 1996). Such findings suggest that there is within-group variability in attributional beliefs.

Similarly, the predictive ability of effort attributions to academic achievement has been noted to vary cross-culturally and to be inconsistent with theoretical expectations that effort attributions can sustain academic performance. For example, Eaton and Dembo (1997) found effort attributions to predict higher levels of achievement, but somewhat unexpectedly, this pattern was only found among their non-Asian participants. Elliott et al. (1999) also found English and American students to report effort to be a major determinant of their academic success; it was noted, however, that these students' commitments to educational endeavors were generally less strong than those of their Russian counterparts. Furthermore, Bempechat and her colleagues generally suggest ability attributions to be a better predictor of academic achievement than effort attributions (Bempechat and Drago-Severson, 1999; Bempechat et al., 1996), pointing to empirical findings that demonstrate that effort attributions are typically either negatively related or unrelated to academic achievement (Holloway, 1988; Marsh, 1984).

As for cross-cultural differences in learning strategies, some studies suggest Asian students to focus more on rote memorization or rehearsal strategies during study (e.g., Purdie and Hattie, 1996), and that use of these strategies does not seem to negatively impact their achievement. However, other studies have found that Asian students do not use memorization strategies more frequently than non-Asian students (Chiu et al., 2007; Neber et al., 2008; OECD, 2010d). For example, Chiu et al. (2007) found that students from Asian countries who reported greater use of learning strategies focused on memorization performed worse academically. Thus, the empirical findings on cultural differences in learning strategies are somewhat mixed. Nevertheless, there continues to be speculation about whether Asian students' conceptions of memorization differ from those of Western students. In particular, it has been suggested that Asian students conceptualize memorization and understanding as interlocking processes that are both important for effective learning outcomes (Kember, 1996; Watkins, 2000), whereas Western students are more likely to view understanding in terms of sudden insight (Dahlin and Watkins, 2000).

In short, this body of work suggests that there may be both universal and culture-specific aspects to students' attitudes and beliefs about learning. However, it is important to note that given the subjective nature of individual attitudes and beliefs about learning, precise measurement is much more difficult to achieve cross-culturally, which often compromises comparisons and interpretation of results. Thus, interpretations of cultural differences in beliefs and attitudes should be made with caution.

For example, it has been noted that the meaning of motivation may vary culturally (Markus and Kitayama, 1991; Zusho, 2008; Zusho and Njoku, 2007). Explanations of differences in meaning typically relate to research on individualism and collectivism, defined, respectively, in terms of autonomous and interdependent self-views, as well as the research on the value placed on personal goals versus group goals, and the emphasis on conforming to communal norms and duties (Oyserman et al., 2002; Triandis, 2001). There is, for instance, evidence to suggest that students from collectivist societies define academic success more in terms of affiliative goals, such as maintenance of good family and social relationships (Chan et al., 2005; Salili, 2009). As a result, it is assumed that individuals from collectivistic societies may experience difficulties separating individual goals from socially based goals (e.g., Bernardo, 2008; Chang and Wong, 2008), and may consequently interpret survey items in a different manner than individuals from individualistic societies.

There is also emerging evidence to suggest that there may be cross-national differences in how individuals respond to Likert scale survey items more generally (Harzing et al., 2012). Specifically, it has been found that East Asian individuals tend to select responses toward the middle of the scale, in comparison to US and Canadian respondents who are more likely to select responses at the extreme ends of the scale (Harzing et al., 2012). Furthermore, unlike the aforementioned large-scale studies of achievement, the majority of cross-cultural studies on attitudes and beliefs employ nonstandardized assessments with compromised reliability and construct validity (McInerney, 2011). Taken together, such findings call into question the construct equivalence of measures used in cross-cultural studies of attitudes and beliefs, further complicating the interpretation of results.

General Trends and Issues

The collective research to date on cross-cultural studies of education has uncovered some important findings about

educational processes and the socialization practices that support them. In general, the findings suggest that academic performance can be explained, in part, by coherent and high-quality instructional practices that promote conceptual understanding. Similarly, home factors such as support of early literacy have been demonstrated to play an important role in students' academic outcomes. Finally, a focus on adaptive motivational beliefs and deeper processing strategies has been found to lead to higher levels of academic performance. Such findings also fall in line with Hattie's (2009) meta-analytic studies, which find that the largest effect sizes associated with achievement are related to quality of teaching, particularly an emphasis on instructional processes that support metacognition and self-regulated learning. Cross-cultural studies of education have also been useful in demonstrating how variation in cultural practices and beliefs impact educational outcomes. Thus, the cross-cultural approach to the study of education has been proven to be advantageous in highlighting both universal (etic) and culture-specific (emic) aspects of education across cultures.

Such findings, notwithstanding, the cross-cultural study of education are a fairly new area of inquiry. As such, there is much that can be improved, both theoretically and methodologically.

Theoretically, Berry et al. (2002) propose universalism to be the most appropriate metatheoretical tradition for the cross-cultural study of differences. Universalism assumes that there are some basic processes that are species-wide and therefore, universal. However, it recognizes the importance of examining larger contextual and societal forces in explaining variation in human behavior, thoughts, and attitudes. Universalism also underscores the importance of reducing ethnocentric methodologies and cultural biases whenever possible, a task that is acknowledged to be difficult but not necessarily impossible (Zusho and Clayton, 2011).

Methodologically, then, one of the greatest challenges facing a universalist approach to the study of education is the operationalization of culture. Many of the cross-cultural studies, in particular those that focus on individual beliefs and attitudes, operationalize culture in terms of race/ethnicity/nation of origin, which can inadvertently promote stereotypes about cultural groups by prioritizing between-group differences over within-group differences. Thus it is important for cross-cultural studies of education to place equal emphasis on investigating both between and within-group differences. For example, the findings of TALIS survey indicate that within-country variation in the intensity of PD can be quite high, and it is greatest in Italy, Korea, Mexico, Poland, and Spain (OECD, 2009). Muthén (1989), too, cautions against the homogeneity assumption – that is assuming that data are obtained from a single population – particularly in studies of education where students often are exposed to varying curricula and instructional approaches, sometimes even within a single school.

It is also clear that the preponderance of research on culture and education to date has selectively focused on restricted populations. For example, Heinrich et al. (2010) highlight that most of the research in cross-cultural psychology focus on individuals living in Western, educated, industrialized, rich, and democratic (W.E.I.R.D) societies, and thus claims about universality of psychological processes may be at best premature, and at worst, simply wrong. Similar claims can be made about the cross-research in education, particularly the studies on individual attitudes and beliefs. Comparisons between Western (typically US or European) and Eastern cultures continue to dominate the field, and smaller scale studies also often rely on convenience sampling (Zusho and Clayton, 2011).

Finally, cross-cultural comparisons are meaningful only to the extent that constructs can be measured reliability and validly across cultures. The various large-scale international comparisons of achievement suggest that it is possible to do this, for the most part, for academic achievement. Indeed, systematic procedures have been put into place to validate assessments of academic achievement. Typically, test questions are developed collaboratively with representatives from participating nations, and field tested prior to use. In addition, the items undergo an extensive translation verification process to ensure that the items have the same meaning across cultures. Procedures for administration of the assessments are also standardized across the various countries. Once the data are collected, care is taken to establish both structural and functional equivalence of the instrument across cultures through factor analytic techniques and by demonstrating that the instrument displays comparable relations with related measures in the hypothesized direction across cultures (Olson et al., 2008).

Such procedures are clearly labor intensive, timely, and costly. Thus, it is hardly surprising that such level of care is not usually seen in smaller scale studies, particularly those that investigate cultural differences in beliefs and attitudes. It is therefore important for future research to continue to investigate and improve the cultural equivalence of its measures before use in comparative studies. In particular, there is great need to standardize the measurement of attitudinal measures such as those related to motivation and learning strategies. It is not uncommon for cultural studies of motivation and learning strategies to employ a variety of instruments, which vary not only in its theoretical orientation but also in the degree of cultural bias inherent in the items. Thus, much of the cross-cultural research is related to differences in students' motivational beliefs and use of learning strategies remain largely uninterpretable.

Cross-Cultural Training in Industrial and Organizational Psychology

Abstract

The focus of this article is on the current state of the literature in cross-cultural training in Industrial–Organizational Psychology. There has been over four decades of research on cross-cultural training; however, the increasing globalization of organizations has presented new challenges in the past decade that need further review. Future areas of cross-cultural training are discussed in relation to issues such as cultural intelligence, virtual teams, and a framework for global leadership.

For over four decades, cross-cultural training (CCT) research has focused on a variety of topics from differences across national boundaries (Berry, 1974; Brislin and Pedersen, 1976) to expatriate deployment (Littrell et al., 2006) to multicultural virtual teams (Brandl and Neyer, 2009). Through the 1990s, there was an intense interest in CCT, which was increased through expatriate assignments. This past decade, CCT has seen the effects of globalization as CCT has been connected to cultural intelligence (CQ) (Earley and Ang, 2003; MacNab, 2012), societal differentiation (Berry, 2008), and leadership appreciation (Holt and Seki, 2012), among other topics. As organizations continue to become increasingly global with people from various cultures working together, it is important to consider factors that influence successful communication and collaboration between diverse groups of people. Although the effectiveness of CCT has been the source of much debate, interest in this topic endures. In this article, we review the major literature on the topic and discuss future research directions.

One challenge that has resulted in studying globalization stems from the semantics used to conduct multicultural research. Early training programs were often referred to as "cross-cultural or intercultural orientation programs" (Bhawuk and Brislin, 2000: p. 162). Terms such as multicultural, cross-cultural, intercultural, and transnational have at times been used to mean the same thing, and at other times referred to different concepts (Holt and Seki, 2012). In a review of the literature through the early 2000s, Littrell et al. (2006) defined CCT as the "educative process used to improve intercultural learning via the development of the cognitive, affective, and behavioral competencies needed for successful interactions in diverse cultures" (p. 356). Other reviews and discussions of cross-cultural research have also defined CCT in a similar manner (e.g., Landis, 2008; Landis and Brislin, 1996; Morris and Robie, 2001). We are adopting the term *cross-cultural* when referring to the study of cultures.

Expatriates have been a focus of many different CCT theoretical and empirical studies (see Bhawuk and Brislin, 2000, for a review). The primary goals of CCT largely include components about how to learn, being adaptable, and processing disconfirmed expectations; with the ultimate aim of making isomorphic attributions rather than rushed assumptions about host culture behaviors (Bennett, 1986; Brislin and Bhawuk, 1999). While many methods can be used to deliver CCT, there is still a lack of information about whether the training organizations conduct is successful (Littrell and Salas, 2005). Studies have found positive relationships between effectiveness of CCT and global assignment adjustment (Brewster, 1995), performance (Caligiuri et al., 2001), and cultural awareness and overall well-being (Black and Mendenhall, 1990). In a meta-analysis examining expatriates, CCT was found to positively relate to performance and adjustment (Morris and Robie, 2001). However, these results were lower than in a previous meta-analysis (see Deshpande and Viswesvaran, 1992), and there was insufficient data to examine differences in training method or amount of time spent in training. Recent research has continued to examine the effectiveness of CCT (e.g., Sanchez-Burks et al., 2007; Okpara and Kabongo, 2011; Puck et al., 2008); however, more empirical work is needed.

The term expatriate has been used throughout the CCT literature to describe people living outside their country of origin. Changes in global organizations show that being a global worker does not necessitate becoming an expatriate. Global workers can include workers that travel for a short period of time (e.g., a one-day business trip), or even workers that remain in their country of origin, but frequently interact with others from another culture (e.g., through phone calls, e-mails, and other virtual communication). Due to these continuing developments in globalization, there is a need to examine workers that do not qualify as expatriates, but nonetheless interact with people from other cultures (e.g., Brandl and Neyer, 2009). Cosmopolitan is a term that refers to someone who has recurrent experience with many different cultures. A global worker today may be a cosmopolitan employee, without necessarily being an expatriate.

Integrating Theoretical Contributions

Many theories have been examined in relation to CCT. While there is no unifying theoretical framework, two important concepts are *culture shock* (stress experienced by people living in a different culture) and *culture distance* (the amount of distance and differences between two cultures; Bhawuk and Brislin, 2000). The two concepts are significant because they appear in many of the frameworks that have been used to examine CCT, and practically they provide ready reasons for conducting CCT (Bhawuk and Brislin, 2000). These two concepts can also be directly linked since more culture shock will be experienced when there is a greater distance between someone's culture of origin and host culture.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.22022-9

U-Curve Theory of Adjustment

The concepts of culture shock and culture distance can be seen in early theories of expatriate adjustment. One such theory is the U-curve theory of adjustment, which is a framework that focuses on how people adjust to being in a new culture (Lysgaard, 1955). The U-curve theory of adjustment consists of four stages of adjustment (honeymoon, culture shock, adjustment, and mastery; see **Table 1**). The theory was named based on the U-shaped pattern that emerged as expatriates adjusted to another culture (Lysgaard, 1955). Adjustment is considered relatively easy during the initial contact with a new culture, as many things are new and exciting. Adjustment becomes more difficult as people become frustrated with the new culture. Following this period of frustration, people become accustomed to the host culture, and adjustment again becomes positive. Recent research has continued to expand on the U-curve theory and examines how time can interact with other factors. Assessing expatriate adaptation during the early phases of international assignments, Firth et al. (2014) found that expatriates high in cross-cultural motivation and psychological empowerment were more likely to demonstrate a higher level of work adjustment in early stages. The results also showed that these same employees need to continually be challenged in their expatriate assignments over time, to maintain long-term adjustment. These findings provide support for screening of potential employees who are higher on these characteristics, to help ease the adjustment process.

The concept of culture distance is reflected in the U-curve theory, as adjustment is supposedly easier if the unfamiliar culture is closer to one's own, as there would be less uncertainty and ultimately less stress (Liu and Lee, 2008). As a more general explanation for CC adjustment that focuses on longer periods of time in a host country, this theory has had much utility. It may help explain the experience of culture and suggest methods of CCT for expatriate adjustment. However, other theories may offer more specific suggestions for CCT methods when preparing for short term or virtual assignments (e.g., working with global virtual teams, working briefly in a company's foreign location, adjusting to an expatriate in their own country).

Table 1 U-curve theory of adjustment

Stage	*Definition*
Honeymoon	Expatriates are interested in all the new and different aspects of the culture. (Occurs during the first week.)
Culture shock	Expatriates become frustrated when trying to adapt to the cultural norms of a new place. They may express anger and hostility to the culture and people. (May last from 1 to 6 months.)
Adjustment	Expatriates are adjusting to the differences in the host culture. (May occur from about 6 to 36 months.)
Mastery	Expatriates are able to behave appropriately in a different culture and have an understanding of the host culture's norms and values. (May occur starting around 25 months.)

As summarized in Liu, C.-H., Lee, H.-W., 2008. A proposed model of expatriates in multinational corporations. Cross Cultural Management 15, 176–193.

Social Learning Theory

Social learning theory (SLT) is a cognitive and behavioral approach that has provided an informative theoretical framework for some CCT methods (Black and Mendenhall, 1990; Morris and Robie, 2001). Proposing that people learn by both observation and experience, Bandura (1977) introduced SLT comprised of four main components: attention (behavior must first be noticed before it can be copied), retention (behavior must be remembered), reproduction (behaviors in memory must be put into action), and incentives (behaviors that are perceived to be positively rewarded are enacted). SLT can inform cross-cultural adjustment, as different behavior patterns may occur across cultures. SLT helps explain how people adjust to different cultures, as well as challenges they face with adjustment. The U-curve theory of adjustment provides a general timeline of adjustment challenges; SLT can help explain what is needed for successful adjustment.

Black and Mendenhall (1990) proposed that SLT can influence cross-cultural adjustment. As SLT suggests that people learn from both observation and experience, these scholars posited that CCT would be most beneficial if it includes models (either hypothetical or simulations) of appropriate behavior. Building on their work, Liu and Lee (2008), described four dimensions of successful cross-cultural acculturation. These four dimensions include self-orientation, other-orientation, perceptual skills, and cultural toughness. Self-orientation increases self-esteem and confidence, which helps people deal effectively with stress and adjust to a different culture. Other-orientation is the ability to develop relationships in other cultures (especially mentoring). Perceptual skills are being nonjudgmental and more willing to align beliefs with a host country. Cultural toughness means adapting to the living standard in another country. Together, this is related to the concept of cultural distance, because adjustment proves more difficult when discrepancies in living standards are larger.

Applying the four-dimension learning process of acculturation with SLT can enhance CCT (Liu and Lee, 2008) by guiding training to incorporate methods, which allow for both observation and behavior modeling (e.g., experiential training, simulations, etc.). Training that incorporates observation and experience can increase successful acculturation by helping participants associate positive outcomes with culturally appropriate behaviors, thereby increasing self-orientation (which has been recently advocated by others (e.g., Chao et al., 2011)). This experience can provide individuals with an initial positive interaction that can help develop future successful relationships, enhancing their other-orientation. Accordingly, when training participants encounter a cross-cultural social interaction that they observed or experienced in training, they are more likely to remember and be able to reproduce this behavior. Perceptual skills can be helped by CCT that includes information about how others view the world (e.g., in culture assimilator training) and draw attention to appropriate models of behavior. Making the assumption that trainees receive accurate information, they will develop accurate cognitive maps of appropriate behavior and be able to envision the appropriate behavior in a cross-cultural interaction (Black and Mendenhall, 1990). The role of toughness in relation to SLT needs further study, but holds much promise.

While cross-cultural scholars have started to integrate theories, there is still more work to be done (Landis, 2008).

Cultural Intelligence

As organizations become more global, theories focusing on how to interact within specific cultures (i.e., SLT and creating cognitive maps) may not fully explain successful cross-cultural interaction. While it is possible to develop cognitive maps for a few specific cultures, it becomes increasingly difficult to retain accurate cognitive maps for many different cultures. Further advancing research on cross-cultural interaction, scholars have introduced the concept of CQ (Ang et al., 2007; Brislin et al., 2006; Earley and Ang, 2003; Ng and Earley, 2006). CQ has commonly been defined as successful adjustment to another culture (Brislin et al., 2006). Alternatively, it has been defined as behaviors that are intelligent or appropriate in different cultures (Brislin et al., 2006), or "adjustments a person can make to be effective across cultures" (MacNab et al., 2012: p. 68). While the exact definitions of CQ vary, the most generally applicable description refers to developing knowledge and enacting behavior appropriate in different cultural contexts (without requiring someone to live in another culture). In the current global environment, people may need to engage in cross-cultural behaviors while working as an expatriate, interacting with an expatriate in their own culture, or are temporarily traveling or engaging in virtual work with someone from another culture. Being able to identify the norms, values, and behaviors of a new culture may be a useful skill and one that can be taught by CCT (MacNab, 2012). Initial research using CQ as a framework for experiential training has provided basic support for CQ (MacNab et al., 2012; Ng et al., 2009).

Among this research, Earley and Peterson (2004) developed a three-part framework for CQ consisting of cognitive/metacognitive, motivation, and behavior components. Cognitive refers to thinking, learning, strategizing, and interpreting information (e.g., the meaning of gestures and have them make sense). Motivation refers to appropriate persistence or realistic goal setting in the context of intercultural interactions, especially when they become confusing or the meaning is not clear, as happens in new contexts. The behavior dimension refers to consciously adapting behaviors appropriate for the cultural context. Using CQ as a framework, CCT methods may be specifically tailored to these three dimensions. These concepts build on the cognitive and behavior components of SLT. Including motivation is an important factor when considering global workers' successful adaptation to cross-cultural situations, even if they have limited existing cognitive maps.

Types of Training

There are two main categories of CCT that are frequently discussed: the *mode* of the training, and the *focus* of the training. The mode of training refers to how information is delivered (e.g., conventional vs experiential training). The focus of training refers to the content or information contained within a training course (e.g., increase cultural awareness, teach culturally appropriate behaviors, etc.). **Table 2** provides an

Table 2 Mode and focus of training

Training mode/focus	*Definition*
Lecture/conventional training	This mode of training involves passive learning. Through this mode, the instructor gives a lecture or talk to participants. It often involves problem-solving activities provided by the instructor, but the problems are not in a realistic setting. This mode is one of the simpler and inexpensive methods of CCT, often delivered as moral training (Bennett, 1986). Compared with no training, this mode may provide benefits to employees in cross-cultural interactions (Bhawuk and Brislin, 2000).
Experiential training	This mode of training was developed in response to the traditional lecture mode of training. These methods include substantial involvement from participants and may include simulation exercises. Simulation games often divide participants into two groups, with each group receiving guidelines about an imaginary culture of which they are members. Helpful for highlighting differences, simulations lack the authenticity of being in a different culture. Other modes of experiential training may include simulating target cultures, or helping participants become more self-aware (Bhawuk and Brislin, 2000; Ng et al., 2009).
Culture assimilator	Cultural assimilator is a training mode where real-life misunderstandings in cross-cultural interactions are described (Fiedler et al., 1971). After reading a critical incident, participants are asked to think about the misunderstandings. Four or five alternative choices of action follow the critical incident. One choice reflects one culture involved in the critical incident and another choice reflects the second culture involved in the critical incident. The other two to three choices are less optimal, but tend to reflect a variety of individual differences (Bhawuk and Brislin, 2000).
Cultural awareness training	Cultural awareness training focuses on teaching participants to be aware of aspects of their own culture that are not necessarily generalizable to other cultures (Morris and Robie, 2001). This can help participants identify how cultures differ from their own.
Attribution training	This mode of training helps participants think in ways more similar to someone of another culture (Morris and Robie, 2001). This can include behavioral modeling, if the participant is expected to interpret the situation from the perspective of a member of another culture (Morris and Robie, 2001). Based on SLT, observation can help people learn about appropriate behaviors (Bhawuk and Brislin, 2000).
Language training	Language training is an important focus because of its significance for cross-cultural adjustment. Although participants may not achieve fluency of the language, gaining the proficiency to communicate at a basic level of the host language, such as exchanging common courtesies, assists in learning another culture (Caligiuri et al., 2001; Puck et al., 2008).

overview of different types of CC training that have been discussed in the literature. These training modes do not necessarily have to compete with each other, but may actually complement each other.

Specific vs General Training

Discussion of training methods emphasizes the classification of training into two main categories: culture-specific or culture-general training. Culture assimilator training is often culture-specific. It provides information to participants about what they might expect in realistic social situations and imparts knowledge about behavioral expectations. While this type of training may be helpful for someone moving abroad and likely interacting with people from one host culture, it may not be as effective for someone regularly interacting with people from a variety of different cultures. Cultural assimilator training is one of the earliest, most widely tested, and most commonly used methods of CCT (Bhawuk and Brislin, 2000; Morris and Robie, 2001). However, limitations of this method's effectiveness have been noted, and this is especially so with the increase in cosmopolitan employees. Thus, more recent research has focused on alternative types of training.

The more general culture awareness training may have greater applicability for someone interacting with many cultures. It is often time consuming and unrealistic for employees to remember how to appropriately interact with many different cultures. Other more general methods of CCT may be of higher utility in improving cross-cultural communication. Cultural awareness training helps employees be more aware of when their cultural assumptions might lead to miscommunication. Thus, it might help employees be aware of important aspects of cross-cultural communication, even if they are unfamiliar with a specific culture. This is illustrated in the work by House et al. (2004) who demonstrate that culture and leadership differences influence management and communication across societies, with much of this research currently assisting in cultural awareness training.

Evaluating the Evidence: Recent Empirical Research in CCT

While many different types of training have been proposed, it is helpful to examine several studies that have compared training processes. In this section, we review more recent work in CCT research. For a review of earlier studies, please see exemplary previous reviews of the theoretical and empirical literature (e.g., Bhawuk and Brislin, 2000; Landis, 2008; Landis and Brislin, 1996; Morris and Robie, 2001; Littrell and Salas, 2005). While empirical studies address many different topics, most studies can be classified as assessing either pre- or postdeparture training, evaluating culture-specific or culture-general training, and addressing conventional or experiential training (see **Table 3** for a classification of select recent articles). In addition to these three components, we have reviewed some recent empirical research focusing on supplementary factors relevant to CCT in more detail.

Non-Expatriate Research

Many research studies (including many of the empirical studies discussed below) examine CCT in relation to expatriates. However, Sanchez-Burks et al. (2007) conducted a study examining American cosmopolitan employees preparing for a short-term six-week international project (where 2 weeks were spent on a short trip working in China or Chile). They examined how cultural assimilator training compared with relational ideology training, focusing on non-expatriates. Overall, their results suggested that relational ideology training (which is a form of experiential training that includes a cultural awareness component) has benefits over cultural assimilator training. While the results supported the benefits of experiential training over cross-cultural assimilator training, it is important to take into account this training was specifically geared toward the three cultures of interest (US as the culture of origin and East Asia and Latin America as the host cultures).

Focus on Culture-Specific and Culture-General Training

Among studies assessing a non-US sample, Puck et al. (2008) examined types of training methods comparing culture-specific with culture-general training. Examining predeparture CCT on adjustment (general, work, and interactional adjustment) of German expatriates working in different countries, a comprehensive measure of training was examined in addition to examining general CCT participation and other factors relevant to adjustment. To create the comprehensive measure, CCT was categorized into four groups (general conventional, specific conventional, general experiential, and specific experiential training), and each participant received a score (1–4) based on the number of types of training completed. The results of the

Table 3 Training components addressed in article[a]

Study	*Pre/postdeparture*	*Culture specific/general*	*Conventional/experiential*
Sanchez-Burks et al. (2007)	Predeparture	Specific	Experiential
Puck et al. (2008)	Predeparture	Specific and general	Conventional and experiential
Lievens et al. (2003)	Predeparture	Specific	Experiential
Okpara and Kabongo (2011)	Predeparture	Specific and general	Conventional and experiential
MacNab et al. (2012)	Postdeparture	Specific	Conventional and experiential (mostly experiential)
Osman-Gani and Rockstuhl (2009)	Pre- and postdeparture	Not specified	Not specified
Liu and Lee (2008)	Predeparture	Specific	Not specified
Tarique and Caligiuri (2009)	Postdeparture	Specific and general	Conventional and experiential

[a]These studies are discussed below or elsewhere in this article.

study suggested that language skills were important in predicting adjustment, but adjustment was not predicted by predeparture training, training length, nor training comprehensiveness. Future research may consider how else data can be collected and analyzed to further aid researchers' and practitioners' understanding of the benefits and limitations of different types of training.

Okpara and Kabongo (2011) further extend the literature on CCT, as they also examined the effects of general conventional, specific conventional, general experimental (experiential), and specific experimental (experiential) training on cross-cultural adjustment. Rather than creating a comprehensive measure of training, they examined the four types of training separately, by assessing expatriate managers working in Nigeria. Overall, they found that all four types of CCT somewhat positively relate to expatriate adjustment (work adjustment, general adjustment, interaction adjustment, and psychological adjustment). Specific experimental training explained slightly larger amounts of variance in adjustment than the other types of training. The relationships between general experimental CCT and adjustment showed slightly weaker associations. This highlights the need for future studies to explore the effects of culture-specific compared to culture-general training.

Inclusion of Contextual and Personality Variables

Rather than just looking at the success of a specific type of training program, some research has also examined personality or contextual factors that impact training effectiveness. Lievens et al. (2003) conducted a study assessing predictors of CCT. They looked at the predeparture experiential training program and language executive training program for European managers being assigned to Japan. Openness predicted training performance, as well as adaptability, teamwork, and communication. Language acquisition (which has previously been related to adjustment) was predicted by cognitive ability. In another study, Osman-Gani and Rockstuhl (2009) examined the relationship between perceived pre- and post-CCT effectiveness, self-efficacy, and adjustment of expatriates working in Asia. Expatriate managers, originating from four different nations, showed that CCT facilitated adjustment through an increase in their self-efficacy. This study helped identify a construct that mediates the effectiveness of CCT on adjustment. Further research should examine other factors that impact successful adjustment in addition to and conjunction with CCT.

Postdeparture Training

In contrast to research that has focused on predeparture training and mainly used survey methodology that relies on participant self-recall to study training, research has also examined postdeparture CCT for expatriates. MacNab et al. (2012) created an experiential training program to help develop the CQ of expatriate university students (students not originally from Australia). They developed a seven-step experiential training program that occurred across 8 weeks and was embedded within an international management course and cross-cultural management course (see MacNab et al., 2012, for the detailed seven-step program). Overall, they found support for this seven-step experiential training program as affecting CQ. They also included individual (e.g., general self-efficacy) and contextual (relationship of someone with the host culture based on contact theory) factors in their study. They found that higher general self-efficacy and more positive contacts with people from the host country increased internalization of CQ. While the results for using a CQ framework and experiential training were positive, future empirical research should further examine CQ as a useful framework for CCT, especially beyond a student population.

Tarique and Caligiuri (2009) argued that in-country CCT would increase cultural knowledge if the training units were divided and disseminated over time. This empirical experiment demonstrated that, similar to predeparture CCT, in-country CCT is another worthwhile intervention for knowledge acquisition for expatriates. Future research would benefit from extrapolating this study beyond the student population utilized in this study. Additional research should also consider if there are forms of postdeparture training that would assist cosmopolitan employees embarking on shorter visits.

Leadership

Interest in cross-cultural leadership has grown exponentially with the advent of globalization. Leaders need to be aware of local pursuits, yet enact global thinking; this is augmented by intensified competition, as companies are able to distribute products and services with increasing ease. The resulting challenges of this increased competition have moved organizations to focus on and invest in leader effectiveness (Caligiuri, 2006). This has resulted in lively discussions of what constitute effective leaders as well as how to develop global leaders (Butler et al., 2012; Holt and Seki, 2012; Ng et al., 2009). Yet attaining a unified definition of a global leader and how to develop global leaders remains somewhat elusive (Bird et al., 2010; Gundling et al., 2011). The number and scope of the tools developed to assess assorted aspects of global leadership is impressive. The list is long with tools such as the Global Mindset Inventory (Javidan and Teagarden, 2011), the Global Competencies Inventory (Bird et al., 2010), CQ (Van Dyne et al., 2008), the Leadership Versatility Inventory (Kaplan and Kaiser, 2003), Transition Leadership Wheel (Bunker and Wakefield, 2006), and the Opposite Strengths Inventory (Thomas and Thomas, 2006) being just a few examples of tools that exist to measure various models of global leadership. Often, leadership training is determined by the outcomes of these assessments.

Most models of global leadership assignments have concentrated on expatriate performance and adjustment, not leadership development (Ng et al., 2009). International assignments are seen as ways to develop global leaders; however, few studies have assessed how leaders turn their expatriate learning into experiences that enhance the effectiveness of their actual leadership. From this perspective, the expatriate assignment functions as a form of CCT. Through the integration of research on CQ and experiential learning theories, Ng et al. (2009) address this question of how and why global leaders learn from their international work assignments. In their model, they propose that CQ will act as a moderator,

increasing the probability that individuals (expatriates or cosmopolitans) on assignments internationally will be part of four stages of experiential learning theory. Further, they contend that participation in these four stages (experience, reflect, conceptualize, and experiment) will allow leaders to developmentally gain from their experiences during their international assignments. Adopting this developmental perspective of expatriates and cosmopolitans (short-term travelers) is worthy of future study.

Some scholars have made compelling arguments that effective global leadership involves a developmental shift beyond the current competency models. Notably, Holt and Seki (2012) argue that such a shift requires us to question the use of some outdated models of leadership; questioning if we have a Western-centric approach to leadership that is applicable in a global context. They acknowledge that a separate stream of literature about intercultural communication has emerged over the past 30 years; however, even when leadership has been acknowledged, the complexities of leadership have not been addressed in these intercultural communication models. Further, Holt and Seki (2012) suggest that today most leaders operate in a global context and that being successful as a leader in a single context does not equate to being an effective global leader. Instead of simply adding a competency to other leadership abilities, being an effective global leader requires a developmental shift. They propose four developmental shifts including: "(a) developing multicultural effectiveness (MCE), (b) becoming adept at managing paradoxes associated with global work, (c) cultivating the 'being' dimension of human experience, and (d) appreciating individual uniqueness in the context of cultural differences" (Holt and Seki, 2012: p. 197). These dimensions cannot be addressed by simply adding competencies to existing leadership models.

There are, however, some existing leadership models that account for cross-cultural differences within their framework (Inceoglu and Bartram, 2012). One of the most noteworthy and comprehensive studies assessing cross-cultural leadership is Project GLOBE (Chhokar et al., 2007; House et al., 2004; House et al., 2014). Carried out in three phases, the first phase was focused on the development of research instruments to assess both societal culture and leadership, which was conducted through the participation of researchers from around the world. From this initial phase, nine cultural dimensions and six global leadership dimensions (comprised of 21 first-order dimensions) emerged. Using the scales developed in the first phase, researchers in the second phase sought to further differentiate attributes of culture and leadership at both the organizational and societal levels focusing on mid-level managers in 62 societies. The second phase was devoted to implementing the surveys to assess the nine core attributes of cultures and six broad dimensions of leadership, with a keen interest in noting whether universal and/or culturally contingent leader characteristics emerged across cultures. Universal leadership characteristics are those seen as important across cultures, while culturally contingent leadership characteristics are seen as concepts influenced by values, beliefs, cognitive schemas, and behaviors that are unique to a culture (Bass, 1997; Den Hartog et al., 1999; Dickson et al., 2012). Culturally contingent leadership characteristics are considered desirable in some cultures, but not others (Den Hartog et al., 1999; Dorfman et al., 2004). The analyses conducted in this stage of the project revealed the existence of both culturally universal and culturally contingent leadership attributes, as well as their impact on leadership. Most recently, the third phase was dedicated to examining the impact and effectiveness of specific CEO leader behaviors on top management team attitudes and firm performance (House et al., 2014). Assessing actual CEO behavior across 24 countries, the results from this phase supported the idea of universal and culturally contingent leader attributes. Together these studies are important for CCT in global leadership, as they greatly enhance our understanding of culture and leadership expectations across many societies. Unfortunately there are a number of practitioners who do not know about this model, and ironically if they do it is the scope of this work that makes it intimidating for practitioners (Holt and Seki, 2012). In order to effectively use the leadership framework promoted in project GLOBE, future CCT methods should be constructed with this model in mind, and be communicated in a way that encourages practitioners to use this research to inform leadership frameworks (e.g., Javidan et al., 2006).

Teams

As multicultural teams become more common, the need for CCT has increased. Cross-cultural team training can help with problems experienced by teams when members interact with other cultures (Littrell et al., 2006). Multicultural teams commonly form through the presence of expatriates in organizations or through virtual teams, with the resulting culture differences affecting the interaction across the teams (Martins et al., 2004). Global virtual teams usually consist of individuals that are from different geographic areas who rarely (if ever) meet in face-to-face communication. With continued technological changes and ever-increasing ways to communicate with people, the need for CCT in virtual teams continues to intensify. Leaders have considerable influence on teams and training for multicultural teams, which impacts the overall team effectiveness (Burke et al., 2005). However, as discussed above, the competencies for intercultural leadership may differ from intracultural leadership.

Since virtual teams rely on technology to communicate, the role of a virtual team leader may be different from a traditional team leader. A leader of a virtual team may need to communicate differently in order to lead, make decisions, and build trust (Meyer, 2010). With online teams, the leader needs to help provide clear direction and be the point person for coordination. In addition to dealing with all interaction occurring through technology, the team leader is often dealing with cultural differences if team members are from different countries and backgrounds. Team members from dissimilar cultures may have different expectations about the norms surrounding appropriate organizational behavior. Factors such as how to arrive at decisions, behaviors that represent trust, and the types of communication that demonstrate politeness and professionalism may differ between cultures (Meyer, 2010). Trust may be especially challenging for global virtual teams engaged in technology-mediated communication (Jarvenpaa and Leidner, 1999). Face-to-face and informal communication have been identified as important for trust, but these forms of

communication are not often part of virtual team interactions (Oertig and Buergi, 2006). As virtual team members are typically cosmopolitan employees (non-expatriates), the intensity and type of training may need to differ from expatriates.

When working in teams with people from different cultures there is a need to adjust to unknown situations and manage uncertainty (Gudykunst, 1998). Brandl and Neyer (2009) propose the importance of cognitive adjustment in CCT, especially as it pertains to newcomers. The concept of cognitive adjustment dates back decades and in this context it reflects team members' ability to understand someone else's perspective (Schutz, 1944). This should be considered when selecting a training program for virtual team members. The usefulness of culture-specific orientation is of limited utility when preparing for the complexities of engaging in multinational team interaction (Earley and Peterson, 2004). General cultural awareness training may be better suited for employees working on cross-cultural teams by enhancing ones' ability to adjust to unknown and uncertain situations (Brandl and Neyer, 2009). This training may help team members be more aware that uncertainty is a normal part of virtual teams. In turn, this makes them feel like they have more support and thus are more willing to explore unknown situations (Glanz et al., 2001), increasing their ability to make mental connections (Osland and Bird, 2000). As virtual teams are progressively either complimenting or even replacing traditional types of global assignments, the necessity for CCT to expand beyond traditional contexts is crucial.

Future Research

Building on recommendations for future research discussed throughout this article, several additional points are worth noting. First and foremost, future research should continue to focus on the evaluation of CCT methods. As more empirical studies are conducted, it would be helpful to examine if there are disparities in the usefulness of different types of training. Other factors to further examine include determining optimal types of training best matched to certain situations (e.g., cross-cultural manager training, training for cross-cultural virtual teams, training for cosmopolitan employees vs expatriates, etc.), pre- vs postdeparture training, individual and contextual factors, as well as training mode and focus.

Future research may also benefit from examining and incorporating, when relevant, components from other training literature such as diversity training. The work on cross-cultural issues and diversity in organizations are interconnected in many ways, yet the theory, research, and practice in the two fields have different frameworks, approaches, and goals. Ferdman and Sagiv (2012) discuss some similarities and differences between CCT and diversity training, and propose how both fields could benefit from a collaboration. CCT focuses on preparing individuals to work in cross-cultural contexts and with people from other countries. Diversity training looks at diversity in organizations in terms of race, ethnicity, gender, or profession. This training addresses issues such as identity, power, privilege, stereotyping, leadership, conflict management, and inclusive behavior. Both fields provide information for learning and interaction, dealing with conflict, and collaboration. CCT can benefit from including other factors (beyond cultural dimensions) and focusing on how those factors can influence interpersonal relationships between people from different cultures. This is an area that may be especially relevant for CCT and research to address.

Future research may further examine how different theories influencing CCT may be integrated to ultimately create more effective CCT methods. Several challenges have been noted when assessing MCE and global leadership development. These challenges include (1) an increasing number of competing frameworks and models; (2) an insufficient level of validation of assessment tools; (3) an inadequate focus on performance of various intercultural models; and (4) along with an insufficient multicultural focus in some leadership models (Holt and Seki, 2012). Future research should focus on integrating performance and multicultural dimensions into the constructs of global leadership competency models.

Increasingly, researchers argue that CCT alone might not always enhance cross-cultural adjustment (Puck et al., 2008; Tarique and Caligiuri, 2009), so companies may want to implement posttraining interventions to assist in learning transfer and adjustment. Future research could assess how organizations might use posttraining coaching, language training, and mentoring as possible interventions to facilitate cross-cultural adjustment. This relates to a final recommendation, which is the need for more longitudinal studies in CCT that encompass many of the aforementioned factors. The more we understand the complexities of CCT, the greater the benefits to the employees and our increasingly global organizations. With the acceleration of globalization, the field is more informed and the challenges ahead more multilayered. Reviewing the field of CCT over the past four decades provides a compelling reflection of what we have learned and where we are progressing.

Abstract

Multilevel analyses of large-scale international studies' data have shown how characteristics at multiple levels (country, family, school, student) influence student achievement. Students in countries that are richer academically outperform other students, in part because they have more resources at home (family socioeconomic status, books, etc.) and school (teachers, schoolmates, educational materials, etc.). Students in countries with greater household inequality, inequality across schools, or economic segregation of richer students from poorer students show lower academic achievement than other students. Cultural values and family characteristics showed interaction effects. Together, these results show the importance of an ecological approach to understanding student achievement.

Introduction

Student achievement on international tests differs sharply across countries. Students in Finland, Korea, Japan, and Canada consistently score over 2 standard deviations higher than students in Indonesia, Panama, Peru, and Kyrgyzstan in mathematics, reading, and science across several international comparisons. These differences in academic achievement might stem from the countries' economic and cultural differences. First, the countries with higher average test scores are generally much wealthier (e.g., as measured by gross domestic product (GDP) per capita) and more equal economically (e.g., income Gini) than the countries with lower average test scores. These differences suggest that both greater educational resources and more equal distribution contribute to greater student learning and academic achievement. Second, the countries within each set are culturally diverse, suggesting that cultural values do not account for differences in test scores.

We examine the antecedents of these differences more systematically by adopting Bronfenbrenner's (2005) ecological framework and discussing the results of previous international studies. Bronfenbrenner (2005) modeled children's interactions with surrounding environments including persons and entities within immediate and direct contexts (such as family and school), the relationships across these contexts, and the broader country context (such as economic and cultural differences). Economic and cultural differences across and within countries can fuel differences in resources across families, schoolmates, schools, and students that influence students' learning opportunities and subsequent achievement. Lastly, we discuss the methodologies involved in collecting and analyzing large-scale international data.

Ecology of Student Achievement

Student interactions with their environment can influence their academic achievement (see **Figure 1**; Bronfenbrenner, 2005). Students have frequent and direct contacts with family (or any immediate context to create a *microsystem*), which offers learning opportunities on which they can capitalize to learn and achieve in school. For instance, students living in families with higher socioeconomic status (SES) tend to outperform other students on achievement tests (Baker et al., 2002). Connections between family and school contexts (or any two microsystems that form a *mesosystem*) can also influence academic achievement. For example, when parents are more involved in children's school activities, their children show higher academic performance (Chiu, 2010). Thus, both the immediate contexts and the interactions among them influence

Figure 1 Ecological model of relationships among country, family, school, and student academic achievement. GDP, gross domestic product; SES, socioeconomic status.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92144-5

students' academic achievement. A more distal context, such as a parent's stress at work, might result in less school involvement and their children's poorer academic performance (links between distal and immediate contexts are called *exosystems*, Bronfenbrenner, 2005). These microsystems, mesosystems, and exosystems are all under the influences of the larger cultural contexts, such as the economy and cultural values of the society (*macrosystem*). For example, students in richer countries showed higher academic achievement, and had stronger links between family cultural communication and academic performance (Chiu, 2007). Hence, ecologies of microsystems, mesosystems, exosystems, and macrosystems can help us understand the factors that influence student achievement within and across countries.

The results discussed in this article are largely drawn from the Organization for Economic Cooperation and Development's Program for International Student Assessment (OECD-PISA; OECD, 2010). OECD-PISA assessed 193 076 15-year-old students from 41 countries in 2000–02; 276 165 15-year-old students from 41 countries in 2003; and 475 760 15-year-old students from 65 countries in 2009 (see **Table 1**). They also asked students and principals to fill out questionnaires. International experts from participating OECD and non-OECD countries defined mathematics, reading, and science achievement; built assessment frameworks; created test items; forward translated them; backward translated them; and pilot tested them to check their validity and reliability (for details and sample items, see OECD 2002, and www.pisa.oecd.org). Participating students completed a 2-h assessment booklet and then, a 30- to 40-min questionnaire.

Studies using OECD-PISA data have shown that differences in student achievement at the country macrosystem, school microsystem, and student levels are all substantial (Chiu and Khoo, 2005). Country macrosystem differences account for 31% of the differences in students' mathematics achievement (24% for reading achievement and 22% for science achievement). Meanwhile, school differences account for 25, 30, and 26% of the differences in mathematics, reading, and science achievements, respectively. Lastly, student-level differences account for 44, 46, and 52% of the differences in mathematics, reading, and science achievements, respectively. Together, these results show the importance of examining factors that influence student academic achievement within a country's ecology.

Economic Differences

Students in countries with greater economic productivity (real GDP per capita) show higher academic achievement (Chiu and McBride-Chang, 2010). Richer countries can raise student achievement through extra resources at the country, family, and school levels (Chiu, 2009). These resources provide students with more learning opportunities. In richer countries, governments tend to invest more in education by building more educational infrastructure (schools, libraries, and museums) and providing better educational resources and teacher training. The availability of these educational resources and opportunities can directly enhance students' learning. Students in richer countries can also benefit indirectly through higher nutritional standards or better health care. These help ensure

students are healthy and have adequate energy when they study, which in turn contributes to better academic performance in richer countries.

Family SES

Families in richer countries tend to have more material, human, and cultural capitals that help their children learn more (Chiu and Khoo, 2005). In richer countries, families often have more educational resources at home (such as books, computers, and tutors), which provide students with more learning opportunities. By capitalizing on these learning opportunities at home, students in richer countries can academically outperform students from poorer countries.

Apart from material support, children also benefit from family members' human capital (Chiu and McBride-Chang, 2010). As the overall education level is higher in richer countries, parents in these countries often completed more years of schooling and have higher aspirations for their children's educational attainment. As a result, these parents encourage their children to study, excel academically, and complete higher levels of education. Furthermore, families with both parents are more likely to have more and better educational resources at home and are more involved in their children's schooling.

Parents in richer countries also often give their children more opportunities to learn cultural knowledge, skills, and values, which contribute to better academic performance (Chiu and Chow, 2010). Cultural possessions at home, such as paintings and poetry books, can highlight the importance of one's culture and facilitate communication about cultural values and norms. This family cultural capital can influence students' academic performance in two ways. First, families with more cultural capital often understand their children's schools better and are more connected with these schools, thereby are more likely to be involved in activities and works in these schools. Second, this cultural capital also helps children better understand school norms and their teachers and classmates' expectations in school. So, these children often behave appropriately in school and have better relationships with teachers and classmates. With greater support from their parents, teachers, and fellow students, these children feel a stronger sense of belonging at school, are more motivated to learn, and have greater academic success than other students (Chiu et al., 2012).

School Resources

At the school level, students in richer countries often have more school resources, teacher resources, and schoolmates who share educational resources with one another, compared to students in poorer countries (Chiu, 2010). Schools in richer countries tend to offer more hours of classroom instruction and have better facilities and teaching materials. By utilizing these school facilities and materials, students in richer countries can learn more than those in poorer countries.

Schools in richer countries often have teachers with higher qualifications and better training (e.g., teacher certification), so their students typically show higher academic achievement (Chiu and Khoo, 2005). These teachers are more capable of using effective teaching methods and raising students' learning interest, all of which enhance student learning. Also, these teachers are more likely to create a supportive classroom atmosphere of mutual respect and caring, and foster students' feelings of being valued for academic efforts, reinforcing their students' school engagement. As discussed earlier, students who have better relationships with their teachers feel a greater sense of belonging at their school and higher academic achievement (Chiu et al., 2012). Furthermore, teachers in wealthier nations are more likely to choose a broader degree of curriculum coverage, a more advanced level of learning activities, and more advanced materials, compared to those in poorer countries. These teachers often have higher expectations of their students and help them realize those expectations through higher academic achievement. Students enrolled in privileged schools are perceived as smarter. Their teachers are likely to have higher expectations of them and are willing to invest more in their learning compared to teachers of other students. Also, teachers can directly or indirectly communicate these expectations to their students, such as adopting a more advanced level of learning activities, thereby affecting their expectations and behaviors. These advantages help students in privileged schools learn more than their counterparts in poorer schools.

Students in schools with good disciplinary climates also show higher academic achievement (Chiu and Chow, 2011). A good disciplinary climate at school provides students with a physically and psychologically safe school environment. These feelings of safety throughout a school contribute to stronger school engagement, and students can concentrate on their learning in this environment. As schools in richer countries often have better disciplinary climates, students in these schools tend to have greater school engagement and higher academic achievement.

Schoolmates

Schoolmates can affect one another's learning through their educational resources and group culture (Chiu and Khoo, 2005). Compared to their counterparts in poorer countries, families in wealthier nations are more educated, are more capable in creating an enriched learning environment, and have more positive attitudes toward formal education. When students share their resources and experiences with their

schoolmates, they learn more and show higher academic achievement. Students with proportionately more high-SES and higher-achieving schoolmates showed better academic performance than those with more low-SES and lower-achieving schoolmates. Higher-achieving students are more likely than other students to value learning and academic success, and thereby support such a school culture at school, which supports other students' learning.

Microsystem Effects in Richer vs Poorer Countries

Country wealth also moderates family or school characteristics' links with student learning (Heyneman and Loxley, 1983). Distinguishing between different types of family resources can explain the apparently contradictory results regarding whether the link between family resources and student achievement is stronger or weaker in richer countries (Chiu, 2007). In richer countries, physical resources at home, such as books and computers, have weaker links to student achievement, but intangible family resources, such as family involvement and communication, have stronger links to student achievement.

As richer countries often have more public physical resources (e.g., library books, museum exhibits) that can substitute for a family's physical resources, these public resources dilute the importance of family learning opportunities, thereby weakening their links to student achievement (*modernization*). Family's physical resources (e.g., books) are strongly linked to student achievement in poorer countries, but much less so in richer countries whose GDP per capita exceeds $16 000 per year (in 1990 US dollars; Gamoran and Long, 2006). While basic physical educational resources (textbooks, maps) are widely available in public arenas (schools, libraries, etc.) in richer countries, these physical resources are not as publicly available in poorer countries (especially schools in Latin American countries), allowing family physical resources to have larger effects on student achievement.

On the other hand, the widespread availability of public physical resources (such as public libraries and museums) in richer countries also raises the value of intangible processes such as family communication (*complementary intangible processes*, Chiu, 2007). Unlike physical resources (e.g., textbooks), processes are intangible and dynamic (e.g., family communication, teacher–student). For example, a student benefits from reading an extra book, but that benefit can be magnified substantially by discussing the book with a parent or a teacher (like a left shoe is more useful with a right shoe). Indeed, children in richer countries often spend more time with their parents due to fewer competing siblings, less parent time on housework, and multitasking parents. Thus, family intangible processes' links to student achievement in richer countries are stronger, while those of family physical resources are weaker.

Inequalities and Their Mechanisms

In addition to a country's total educational resources, the distribution of these resources influences student achievement (Chiu and Khoo, 2005). Specifically, inequality of family income (*family inequality*), inequality of school resources (*school inequalities*), and degree of separation of rich students from poor students into different sets of schools (*economic segregation*) show effects on student achievement.

Family Inequality

National and school policies can influence students' family inequality, school inequalities, and economic segregation (Chiu, 2009). Regressive taxes, corruption, and a weak legal system can increase inequality of family incomes (*family inequality*), while progressive taxes, social welfare, transparency, and health care and safety standards (e.g., clean water) can reduce it. Influenced by national policies, family inequality reduces overall student achievement through fewer overall educational resources, diminishing marginal returns, and privileged student bias.

Greater family inequality results in less overall investment in educational resources, which reduces academic achievement among both poor and rich students (*fewer educational resources*, Chiu, 2009). The elite of very unequal countries can send their children to private schools, so they might advocate for fewer public school resources and greater family payment for each child's education. Even if the elite send their children to public schools, they have many more educational resources (e.g., books or tutors) at home than others, so they may not advocate for more public spending. When students' families have to pay for much of their education, poorer parents cannot afford the optimal amount of education for their children, resulting in suboptimal educational resources in the society. As a result, poorer students have fewer educational resources and learn less, thereby reducing overall achievement.

Family inequality lowers overall student achievement due to diminishing marginal returns (Chiu and Khoo, 2005). Consider a thirsty woman and two glasses of water. She greatly values the first glass of water and drinks it all. Her thirst quenched, she does not finish the extra glass of water, revealing its lower value (*diminishing marginal returns*). Likewise, rich students have more educational resources than poor students do, and a richer student typically benefits less from an extra book than a poorer student does. With a less equal distribution of a fixed set of resources, richer students have extra resources and obtain less utility from them compared to poorer students who have fewer resources, resulting in less efficient utility of resources and lower education outcomes overall.

In school systems with larger distribution inequality, privileged parents have more incentive to use their capital to get more educational resources for their children (Chiu and Khoo, 2005). Schools that allocate more resources to richer students exacerbate the effect of disparities in income. Because of diminishing marginal returns, greater *privileged student bias* results in lower overall student achievement.

Some methods of resource allocation (open markets, cronyism, and social–cultural affinity) allow privileged parents to move more resources to their children compared to others (uniform or truly random allocations; Chiu, 2009). In open markets, privileged parents can use their financial capital by moving to a rich neighborhood to give their children richer schoolmates for example. They can use their social capital through cronyism, for example, by asking the vice principal to

assign their child to a course with a better teacher. Through their human capital, privileged parents can teach their children social norms and cultural capital to create greater affinity with teachers. Teachers have higher expectations of these students and often give them more attention and assistance (*cultural gatekeeping*).

School Inequality

Countries with greater family inequality often have greater school inequalities (Chiu, 2010). A system of strictly free market, private schools without national standards (e.g., no teacher certification) can magnify the impact of family inequalities as richer families pay higher tuition for their children to attend richer schools with more educational resources (teacher quality, computers, richer schoolmates, and so on). In contrast, a universal public school system with required teacher certification standards can reduce inequalities among students.

Schools with greater inequalities showed lower academic achievement among mostly poor students (Chiu, 2009). As with family inequality, school inequalities are accompanied by diminishing marginal returns, which result in lower overall achievement among poorer students. Furthermore, school resources (books, teachers, classmates) and family resources (books, siblings, parents) are mostly equivalent substitutes for one another; richer students often have a book at home that is largely equivalent to a book at school, so the latter's absence does not affect the richer student's academic achievement (*substitution effect*). Hence, fewer school resources did not reduce richer students' academic achievement.

Economic Segregation

Economic segregation is also related to academic achievement (Chiu and Khoo, 2005). The degree of economic segregation differs across school systems. In the US, schools are often funded through local taxes, so richer students often attend one set of schools in richer neighborhoods, while poorer students attend a separate set of schools in poorer neighborhoods. In contrast, rich and poor students often mix together in the same schools in other countries such as Japan and Finland. Economic segregation reduces interactions between richer and poorer students, resulting in less diverse interactions for all students. Less exposure to experiences of students in other economic strata results in less shared knowledge, less learning, and lower academic achievement among all students (*diversity effect*; Chiu, 2009).

Cultural Differences

Countries have different cultural values and the ways they address basic societal issues (Hofstede, 2003). People learn these values through both formal socialization, including direct teachings of parents and teachers, and informal socialization, such as daily exposure to social norms. Among different cultural values, two basic societal issues are particularly important to students' academic achievement, and they are the degree of hierarchy and obedience to authority vs equality (hierarchical vs egalitarian), and favoring group interests vs individual interests (collectivism vs individualism). A hierarchical nation emphasizes authority, obedience and hierarchical status (e.g., Russia), while an egalitarian country emphasizes equal status and treatment of one another (e.g., Sweden). Also, a collectivist society favors group interests (e.g., Hong Kong), while an individualistic nation favors individual interests (e.g., New Zealand).

Cultural values did not directly affect students' test scores, but they interact with the effects of family characteristics on academic achievement (Chiu, 2007). As egalitarian societies have less rigid societal status, individuals have greater economic and social mobility through their individual skills and talents. Thus, students in these countries often view academic achievement as linked to future success, so they are more likely to study harder and achieve greater academic success. Furthermore, students are more motivated to make better use of their resources in egalitarian societies, yielding stronger links between family resources and student achievement (*egalitarian motivation*). Specifically, family SES and numbers of books at home had stronger links to academic achievement in more egalitarian cultures.

Meanwhile, students in collectivist societies are more inclined to cooperate, support, and learn from their schoolmates and family members (Inglehart et al., 2004). In more collective societies, people tend to rely more on their extended family members who often live nearby, and so students are more likely to benefit from them. As extended family resources dilute the effects of immediate family resources in collective societies, the link between immediate family resources and academic achievement is weaker than in individualistic societies (*collectivist dilution*; Chiu, 2007). Specifically, single parents, family SES, resident grandparents, and birth order were all less negatively linked to test scores in more collectivist cultures.

Methodological Issues

International studies require appropriate data samples, precise test and questionnaire designs, and suitable analytic tools (see **Table 2**; Chiu, 2010). Ideally, data samples are representative of the populations, with few sampling errors and no missing data. Meanwhile, tests and questionnaires aim to maximize data validity by minimizing measurement errors and maximizing equivalence across countries. Tests seek to optimize coverage of target concepts and skills. Analyses can model multiple levels of data, cross-level moderation and mediation, and multiple outcomes.

Data Samples

To create a representative sample of a country, researchers typically categorize schools (e.g., by neighborhood SES), randomly select schools from each category, and then randomly select students from each selected school (*stratified samples*) with corresponding *weights* for each student. To reduce sampling error, researchers select several subsamples to create *plausible values*, which must be modeled in the subsequent analyses.

In such a huge data collection enterprise, missing data are typically unavoidable. Missing data can reduce estimation

Table 2 Strategies to address each analytical difficulty

Analytical difficulty	Strategy
● Representative sample	● Stratified sample
● Sampling error	● Plausible values
● Missing data	● Markov Chain Monte Carlo multiple imputation
● Measurement equivalence of test and questionnaire items	● Forward and backward translation of each item; ● Multigroup Rasch model
● Wide coverage of skills while minimizing student fatigue and learning effects	● Balanced incomplete block test
● Competence estimates from test answers	● Factor Analysis ● Item Response models
● Measurement errors on questionnaires	● Factor Analysis ● Item Response models
● Nested data of students within schools within countries	● Multilevel analysis (aka Hierarchical linear modeling)
● Cross-level moderation	● Random effects model
● Indirect, mediation effects	● Multilevel mediation tests ● Structural equation models
● False positives	● Two-stage linear step-up procedure
● Simultaneous outcomes	● Multivariate outcome models

efficiency, complicate data analyses, and bias results. Markov chain Monte Carlo multiple imputation estimates the values of the missing data, which addresses these missing data issues more effectively than deletion, mean substitution, or simple imputation.

Tests and Questionnaires

Tests and questionnaires have special designs. Test items are divided into overlapping subsets (*subtests*) in a *balanced incomplete block* test design to (1) maximize coverage of target concepts and skills, (2) reduce student fatigue, and (3) reduce test-learning effects. To reduce measurement error on questionnaires, multiple items were used for each theoretical construct (e.g., SES) to create an index that is more precise than any single variable.

To test for data validity, translations and a multigroup Rasch model are used. Each item on a test or a questionnaire is forward translated into the new language of the test by one person and then backward translated by another to check the quality of the translation. Multigroup Rasch models for each item in each country test whether the measures are equivalent across countries. Unlike factor analysis, a multigroup Rasch model has the advantages of requiring only one invariant anchor item across countries and modeling heterogeneous use of the ordinal rating scale.

To capitalize on the special designs of the tests and questionnaires to reduce measurement error, researchers use factor analyses and item response models. A factor analysis tests whether a set of test items reflects one or more underlying achievement dimensions (e.g., mathematics achievement vs reading achievement). For each construct, its test item's characteristics (difficulty, discrimination, chance) are estimated with an item response model. Some test items capture higher levels of a construct more precisely, while others capture lower levels of a construct more precisely (*item difficulty*). Likewise, each test item's precision for distinguishing each level of a construct can differ (*discrimination*). The chance parameter models the likelihood of successfully guessing a correct answer for a test item.

For questionnaire items, factor analysis and item response models are also used. A factor analysis tests whether a set of questions that appears to test similar constructs (e.g., mother's and father's years of schooling) reflects one or more underlying constructs (e.g., SES). For each construct, its questionnaire item's characteristics (difficulty, discrimination) are estimated with an item response model. Some questionnaire items capture higher levels of a construct more precisely, while others capture lower levels of a construct more precisely (*item difficulty*). Likewise, each question's precision for distinguishing each level of a construct can differ (*discrimination*).

Analysis

As the data are nested (students within schools within countries), a multilevel analysis of weighted, plausible values is needed (also known as hierarchical linear modeling). Students in the same school (or country) likely resemble one another more than students in different schools (or countries, *group heterogeneity*). Applying an ordinary least squares regression to nested data yields biased standard errors. In contrast, a multilevel analysis yields appropriate standard errors. For multilevel analyses, at least partial metric and partial scalar invariance of the measurement instruments are needed to compare latent means and regression coefficients over countries (Davidov et al., 2011).

Testing many hypotheses increases the likelihood of a false positive. To control for the false discovery rate, the two-stage linear step-up procedure is used, which outperformed 13 other methods in computer simulations.

As the data are nested, cross-level moderation and mediation tests are needed. A random effects model precisely tests whether the relationship between an explanatory variable and an outcome variable differs across contexts or interacts with another explanatory variable via random effects models. The empirical M-test corrects for potential nonnormal distributions in nested data by using multiple data simulations.

Multivariate outcome models can be used to analyze multiple outcome variables simultaneously (e.g., mathematics, reading, and science tests). Ignoring the relationships among outcome variables can result in correlated residuals that underestimate standard errors. Multilevel, multivariate outcome models address this issue to yield proper standard errors.

In short, international studies require high-quality data, precise tests and questionnaires, and appropriate analytic tools. Stratified samples, representative weights, plausible values, and Markov chain Monte Carlo multiple imputation can improve their data quality. A balanced incomplete block test design, construct indices based on sets of questionnaire items, forward and backward translations, multigroup Rasch models, factor

analyses, and item response models can help increase data validity. Lastly, multilevel, multivariate outcome analysis of weighted, plausible values; two-stage linear step-up procedure; random effects model; and empirical M-tests can be used to analyze these data.

Future Research

The availability of international data sets, their data beyond student achievement, and the potential expansion of databases portend tremendous growth in international research in the coming decade. Research on international comparisons of education is accelerating through large, international teams of scholars collecting enormous, high-quality data sets and making them freely available and easily accessible by Website downloads (e.g., www.pisa.oecd.org). Thus, scholars can use them readily both for research and teaching. The data can benefit young scholars, especially students, by providing data with which they can immediately test their hypotheses.

While most research has focused on the student test data, the extensive student questionnaire data present invaluable opportunities for analyses of other aspects of schooling aside from achievement, such as social relationships, student discipline, emotional sense of belonging at school, and so on. Furthermore, the questionnaire responses of parents, teachers, and principals can be examined as outcome variables in addition to their relationships to student outcomes.

Future research will link large-scale, cross-country data sets and create longitudinal data sets. Linked data sets combine a student achievement database with school databases or country databases to model the effects on student outcomes of school or country variables that were not available in the original student database. Longitudinal data sets follow individual students, which both control for individual student differences for more precise results and allow testing of hypotheses involving time. Altogether, these are promising developments for large-scale international research.

Crossover Designs

Michael G Kenward, London School of Hygiene and Tropical Medicine, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In a crossover design, each unit is randomized to a sequence of experimental conditions or treatments, with the aim of comparing the effect of individual treatment assignment. When within-unit dependence of the outcome is relatively large, such designs can be much more efficient than parallel group studies with the same number of units. One potential issue with such designs is the possibility that earlier treatment responses can affect later outcomes, the so-called carryover effect. Many possible designs exist, ranging from the simple two-period two-treatment designs to those with many treatments and periods. Efficient designs can be constructed that allow adjustment for carryover effects, but only when expressed in particular, limited, mathematical forms. Data from crossover designs are examples of conventional repeated measures, and analyses can be taken from the range of tools available for these, both with continuous and discrete outcomes. Methods that perform well in small samples are essential because of the common use of such small sample sizes in the crossover context.

Introduction

In the familiar randomized parallel group design, each experimental unit, often a subject, is randomly allocated to one of the experimental interventions, or treatments. By contrast, in a crossover design, each unit is randomized to a *sequence* of treatments; a special case of a *repeated measures* design. In spite of this difference, however, the goal of a crossover study, in nearly all settings, remains the same as that of a parallel group study: to compare the effects of the *single* treatments, not the effects of the *sequences* to which the units have been randomized. Hence, in a crossover trial, units are not randomized to the interventions under comparison, and this has important implications for the design, analysis, and interpretation.

The main advantage of a crossover design, over the parallel group, is the opportunity it provides to compare the effects of treatments within-units. That is, any component of a unit's response that is consistent across time is removed from the treatment comparison. The degree of such consistency is measured by the within-unit, or intraclass, correlation. As a consequence, the precision of the treatment effect from a crossover study will typically be larger than that from a parallel group study with the same numbers of units, and will have the greatest advantage when the within-unit correlation is high. In this respect, the crossover study has much in common with a blocked or matched study in which the unit is the blocking/matching variable. A second advantage in terms of precision per unit, which is less often remarked in this context, is that each unit contributes observations under more than one treatment. So, although a simple baseline measurement can be used to remove between-unit variability in a parallel group trial, the precision will still be substantially less than the corresponding crossover trial. The main reason therefore for considering the use of a crossover design is the ability to produce sufficiently high precision with comparatively small numbers of units. Indeed, there are examples where the precision from a crossover trial is in orders of magnitude greater than a parallel group study of equivalent size.

This potential gain in precision comes with a price, however. Clearly, such a design cannot be used with treatments that irreversibly change the condition of the unit.

Once treatment has ceased, the unit must return to the original condition, at least approximately. For the same reason, such designs are only appropriate for measurements that are reasonably stable over time. It is always possible with such a design that some consequence of earlier treatment may still be influential later in the trial. In the crossover context, this is called a carryover effect. In principle, such effects may be due literally to a physical carryover; a drug is a good example of this possibility. Or, it may be due to a less direct cause such as a psychological effect of prior treatment. The key point is that units in the second and later periods of a crossover trial have systematic differences in their past experience in the trial. This potential source of bias is akin to confounding in an epidemiological study and implies that to some extent the analysis of data from a crossover trial will inevitably rely more on modeling assumptions, and less directly on the randomization, than a conventional parallel group study. This issue is particularly acute in the so-called two-period two-treatment or 2×2 or AB/BA design. This is the simplest crossover design and is particularly common in a clinical setting. In this design, each unit receives two different treatments, which are conventionally labeled as A and B. Half the units are randomized to receive A first and then, after a suitably chosen period of time, *cross over* to B. The remaining units receive B first and then cross over to A. Because this particular design is commonly used, and because it raises very special issues in its own right, the next section is devoted specifically to it. There are many other so-called *higher-order* designs, with more than two periods, and/or treatments, and/or sequences. The choice of such designs and associated analyses are considered in the remaining sections. Much of what follows is elaborated in two standard texts on crossover trials, Senn (2002) and Jones and Kenward (2014), and we refer the reader to these for further details.

The Two-Period Two-Treatment Design

In the two-period two-treatment, or 2×2, design each unit is randomized to one of two treatment sequences A then B, or B then A. The term period is used for the time interval in which the unit receives a particular treatment, hence this is a two-

period design. In a clinical setting, there is often an additional period between the two treatment periods in which units do not take either treatment, known as the washout period. Its purpose is largely to reduce the chance of bias due to carryover. We return below to such concerns, as well as to the incorporation into the analysis of measurements made in the washout period. To begin with, it is assumed that there is no carryover effect present, and no treatment-by-period interaction, and the focus is on the use of the measurements made only in the treatment periods. To represent these, we introduce some notation. Let Y_{ijk} denote the outcome from unit k, $(k = 1, \ldots, n_i)$ on sequence i, $(i = 1, 2)$ in period j, $(j = 1, 2)$. It is assumed that n_i units are randomized to the ith sequence. This outcome might, for example, be a summary measure from all or part of the relevant treatment period or a measure from a particular time, often the end, of the period. When the treatment effect is estimated from these, it is necessary to acknowledge the repeated measures structure of the design. This implies that it is not possible to rule out a priori an overall change in response between the two periods: the so-called period effect. Hence on design considerations alone, it is necessary to adjust for a period effect in the analysis. It is the requirement for this adjustment that means that, in general, any crossover design must have at least as many sequences as treatments.

Fortunately, the adjustment is very simple to do in practice, particularly so in the 2×2 design. Denote the averages from the four sequence-by-period means by $\overline{Y}_{ij}$. The B–A mean treatment difference, adjusted for period effect (τ say) is then estimated as

$$\widehat{\tau} = \frac{1}{2}\left(\overline{Y}_{12} + \overline{Y}_{21} - \overline{Y}_{11} - \overline{Y}_{22}\right) \qquad [1]$$

To make inferences about τ we note that, if we define the within-unit differences $D_{ik} = Y_{i2k} - Y_{i1k}$, then $\widehat{\tau}$ is simply the mean difference of these between the two sequence groups:

$$\widehat{\tau} = \frac{1}{2}\left(\overline{D}_2 - \overline{D}_1\right)$$

For inferences therefore standard two-sample procedures can be applied to the differences D_{ik}. Most commonly, the standard two-sample t-test framework is used to provide test statistics, confidence intervals, and power calculations. For the latter, it must be remembered that the relevant variance is that of the within-unit differences D_{ik}, not the raw observations Y_{ijk}. Alternatively, nonparametric procedures can be applied to the same differences.

It can therefore be seen that, with complete data, under the assumption of no carryover or treatment-by-period interaction, the analysis for the 2×2 design is a very straightforward application of a two-sample procedure applied to the within-unit differences. However, there has long been concern in this setting about the carryover assumption. If there is such a carryover effect, the simple estimator in [1] will be biased for τ. An early and influential paper, Grizzle (1965), made the suggestion that the analysis should therefore begin with a test for the presence of such a carryover and, only if nonsignificant, should the estimator in [1] be used. If found significant, on the other hand, then the treatment effect should be estimated from the first period data only (i.e., $\overline{Y}_{21} - \overline{Y}_{11}$). This two-stage procedure was widely adopted. However, it suffers from two very serious problems, which mean, in practice, it should be avoided.

The first problem lies with the power of the initial test for carryover, which, in the 2×2 trial, turns out to be equivalent to a test for treatment-by-period interaction. This test parallels that for the direct treatment effect above, but is calculated using the unit sums $S_{ik} = Y_{i1k} + Y_{i2k}$ in place of the differences D_{ik}, and there is no factor of 1/2. Suppose that, an observation Y_{ijk} has variance σ^2, and the within-unit correlation is equal to ρ, then $\mathrm{V}(D_{ik}) = (1-\rho)\sigma^2$ and $\mathrm{V}(S_{ik}) = (1+\rho)\sigma^2$. It follows that the ratio of the variances of the carryover estimator and the direct treatment estimator is

$$R = 2 + \frac{\rho}{1-\rho} \qquad [2]$$

As the within-unit correlation increases, this ratio grows without limit. In a typical crossover setting, the within-unit correlation is large, and the trial is powered for the direct treatment effect, leading to comparatively small numbers of units. The ratio [2] grows without bound as ρ increases, and this means that the variance of the carryover estimator can become very large in a typical trial. Consequently, the power for the carryover effect is often very low indeed. As an example, consider the 2×2 crossover trial on treatment for asthma described in Jones and Kenward (2014, Section 2.10). This had 17 units with the outcome, a lung-function measure: forced expired volume in 1 s. In this trial, ρ was estimated as 0.96, with corresponding R equal to 28.6. As a consequence, 28.6 times as many units (476) would have been required to estimate the carryover effect with the same precision as the direct treatment effect and, in terms of power in the actual sample, the test for carryover is effectively useless. Because of the typical low power of the test for carryover, it was suggested in the original two-stage proposal (Grizzle, 1965) that this might be made at a higher nominal size, such as 10%. However, any such modification is insufficient in most cases to rescue this test and negative results from such low-powered tests convey no useful information.

The second major problem with the two-stage procedure was pointed out by Freeman (1989). Because of the statistical dependence between the preliminary test for carryover and the first-period treatment comparison, the two-stage procedure leads to both bias in the resultant treatment estimator and increases the probability of making a Type I error. In other words, the actual significance level of the direct treatment test is higher than the nominal one chosen for the test. The first-period comparison would only be unbiased were it always used, or chosen for a reason independent of it. Unfortunately, this is not the case in the two-stage procedure, in which it is only used following a significant (hence large) carryover. Although attempts have been made to circumvent this problem, there is no solution that does not involve introducing information about the carryover effect that is not contained in the data. Given that a crossover trial will be powered for within-unit estimation of the treatment effect and so will not have the sensitivity to provide useful information on the carryover, it has been argued that the best approach to this problem is to take all practical steps to avoid possible carryover, such as using washout periods of adequate length between the treatment periods, and then assume that this effect is negligible and use the simple estimator in [1] and the associated analysis. This in turn requires a good working knowledge of the treatment

effects, which will most likely be based on prior knowledge of, and/or the mechanisms behind, these.

Many 2×2 trials have additional measurements taken before the first treatment period, at the end of the so-called run-in period and at the end of the washout period. These are called baseline measurements, noting that, in contrast to a parallel group design, such baseline measurements (the ones from the washout period) can be collected after randomization. Although it is tempting to introduce these baselines into the analysis in a fashion analogous to a parallel group design, for example using change from baseline as response and/or with baselines as covariates, some care is needed in their introduction. Because of the within-unit nature of the primary analysis, these baselines do not have the usual role familiar from parallel group studies. Between-unit variability as existing in the treatment periods is already eliminated from the treatment comparison and for the baselines to make a contribution over and above this, they must explain additional variability. This will happen only when the correlation between an outcome Y_{ijk} and its associated baseline is considerably greater than between the two outcomes Y_{i1k} and Y_{i2k}. This might happen, for example, if the time interval between the treatment measurements is much greater than between baseline and associated treatment measurement. On the other hand, if the correlations among the four measurements from a unit are all similar, then not only will no improvement in precision be obtained from using baselines in the analysis, but also their introduction is likely to actually *decrease* precision. For example, if all within-unit correlations are exactly equal, then the variance of the treatment estimator obtained using the change from baseline as response is exactly double that of the estimator [1] that uses only the treatment outcomes.

The baselines have much greater potential value when estimating the carryover effect, because they can be used to eliminate between-unit variability from this. For further details, we refer to Jones and Kenward (2014: Section 2.11). A further and important issue arises with the use of baselines in crossover designs that applies both to the 2×2 and higher-order designs. This is discussed below when model-based analyses are considered.

The very simple analyses so far described rest on the assumption that the data are continuous. The analogue of the two-sample t-test of the differences D_{ik} for binary data is given by the Mainland–Gart test, which is a simple extension of McNemar's test that incorporates adjustment for a possible period effect. The Mainland–Gart test is just that for association in a 2×2 contingency table that is constructed as follows. When the outcome is binary, each unit presents one of four possible responses for the two periods (Y_{i1k}, Y_{i2k}): (0,0), (0,1), (1,0), and (1,1). The so-called nonpreference responses (0,0) and (1,1) are discarded and the columns of the table are correspond to the *preference* responses (0,1) and (1,0). The rows are then given by the two sequence groups:

	Outcome	
Sequence	*(0,1)*	*(1,0)*
AB	n_{11}	n_{12}
BA	n_{21}	n_{22}

In this table, n_{11} is, for example, the number of units who responded with a 0 in period 1 and a 1 in period 2 in sequence group AB. The test for treatment effect, ignoring carryover, is then the test for association in table; for example Pearson's chi-squared statistic. If numbers in this table are small, as they often are in a crossover trial, especially after discarding the (0,0) and (1,1) responses, then a small-sample exact procedure such as Fisher's can be used. Other outcomes, such as ordinal and count are best handled using appropriate model-based methods, to which we return briefly below.

Finally, it should be noted that the simplicity of the analyses met so far rests on the completeness of the data. If units drop out of the trial, then there will be left some singleton measurements. The decision may be made leaving these out of the analysis, and use the same simple procedures with the completers. In terms of precision, if the within-unit correlation is high, then these singleton measurements contribute very little to the direct treatment effect and little is lost through their omission. On the other hand, to use the singletons in the analysis, a model-based analysis is needed that can combine within- and between-unit information. Suitable tools for this are met below.

Higher-Order Designs

As argued above, that, when using the 2×2 crossover design, it is best to assume that any carryover effect is negligible. This is because, in nearly all examples of its use, the design provides insufficient information on such a carryover to allow either adjustment for it or its elimination. Several higher-order designs for two treatments have been proposed that attempt to circumvent this problem. However, to be effective, these require strong assumptions about the nature of the carryover effect. These designs have extra sequences and/or extra periods. For example, extending the design to three periods means that the following three alternative designs with two sequences might be considered: ABB/BAA, ABA/BAB, or AAB/BAA. In the absence of a carryover effect, these designs are effectively equivalent for estimating the direct treatment effect. However, more importantly, they also allow the treatment effect to be estimated using within-unit information after adjustment for a particular form of simple carryover effect, something that is impossible with the 2×2 design. In these circumstances, the three designs behave rather differently in terms of precision, and it turns out that the first design, ABB/BAA, is most efficient among the three. At first sight, this appears to provide a solution to the main problem associated with the 2×2 design. However, this advantage depends on strong and potentially unrealistic assumptions about the form of the carryover: namely that the carryover effect is the same whether carryover is occurring into A or into B. This is an example of a general problem with the design of higher-order crossover design: many arrangements are possible and some can be shown to have particularly good mathematical properties under specific modeling assumptions (especially concerning carryover). But these assumptions themselves are not usually open to sufficiently precise assessment from the data generated by the design, so the same general issue that surrounds the 2×2 design is still present, albeit in a more complicated and less

accessible form. For this reason, great care is needed in interpreting the term 'optimal design' in this setting.

The higher-order two-treatment designs can be extended in a number of ways with more sequences and periods, allowing further effects, such as treatment-by-period interaction, second-order carryover, and carryover-by-treatment interaction to be estimated. They are not widely used in practice, however, beyond very specific application areas.

For a design with more than two treatments (t say) it is usual, where practical, for each unit to receive all treatments, implying that the number of periods is equal to t. In addition, because adjustment for period effects is the norm, it is important for reasons of efficiency to balance treatments within periods. A design in which this balance is exact is called a Latin square design.

In such a design, every unit receives each treatment and each treatment occurs equally often in each period. This is an example with four sequences, four treatments (A, B, C, and, D), and four periods:

	Period			
Sequence	*1*	*2*	*3*	*4*
1	A	B	C	D
2	D	A	B	C
3	C	D	A	B
4	B	C	D	A

A design based on this scheme would have a multiple of four units in total with one quarter randomly assigned to each sequence. Provided carryover is not a concern, any such square would be equally efficient for estimation of the direct treatment effects, and similar arrangements can be constructed with any number of treatments.

If, on the other hand, adjustment is to be made for carryover, then this design is very poor. It can be seen that each treatment is preceded by the *same* treatment in the three sequences in which it does not occur first. This means that treatment and carryover effects are highly nonorthogonal and adjustment causes a severe loss in precision. This can be largely resolved by choosing a special Latin square arrangement in which every treatment is preceded equally often by each other treatment. For example, in the four treatment case we might consider the following design:

	Period			
Sequence	*1*	*2*	*3*	*4*
1	A	B	C	D
2	B	D	A	C
3	C	A	D	B
4	D	C	B	A

Latin square designs with such balance are called Williams square designs (Williams, 1949). In fact, they are only square when t is even; for t odd, a Williams square design has $2t$ sequences. Examples of Williams squares designs for a range of values of t are given in Jones and Kenward (2014: Chapter 4). Even if adjustment for carryover is not to be used in the analysis, these designs have the advantage of having a degree of robustness to carryover: an unadjusted analysis will produce less-biased estimates of the direct treatment effects even when carryover is present in the data compared with the earlier Latin square design. However, as above, these remarks refer strictly to a specific form of carryover: simple first order. Many alternative forms are conceivable, and a design that is chosen with one type in mind may be poor for another.

Not all higher-order crossover designs are appropriate for undifferentiated sets of treatments, as are the Williams squares. There are particular designs for comparisons with a control, and for factorial designs. Details of these and other special designs can be found in Jones and Kenward (2014: Chapter 4). It is a good choice where possible to have each unit receive every treatment in a crossover trial, as in a Williams square. Designs for which this is not true are sometimes called incomplete designs, and these are generally less efficient.

Model-Based Analyses

The simple two-sample analyses that were used above with complete data from the 2×2 design need generalization for other designs and for incomplete data. Because the data from crossover trials are examples of repeated measures data, we can draw on the body of analysis tools available for this setting (e.g., Verbeke and Molenberghs, 2000; Molenberghs and Verbeke, 2005). Accordingly, with continuous data, linear regression models for dependent data can be used and, for discrete data, the appropriate analogues of these. In many settings with continuous data, we can in fact use very simple, ordinary, regression models by analogy with randomized block analyses. With crossover trials, one normally expects fairly stable responses over time, and it is often sufficient therefore to capture the within-unit dependence through the introduction into a linear model of a simple unit effect. This effect can be treated as fixed or random in the analysis. To understand the implications of choosing one or other of these, we need to consider the source of the information on treatment effects in the given crossover design. It is natural and convenient to divide this information into two independent components: the between- and within-unit information. The between-unit information is that provided by the sums (or means) of all the observations from each unit. By contrast, the within-unit information is that contained among all differences of observations from each unit. The information available from these two sources depends on both the design and the model fitted. This division of information is also dependent on the size of the within-unit correlation: as this correlation increases, the comparative variability of the between-unit sums grows. In terms of models, in many settings, a very simple, or minimal, form will suffice. This will include, in addition to the unit effects, categorical effects for period and treatment. On occasion, this will be augmented by carryover effects and, more rarely, other terms. In a fully balanced Latin square design, with the minimal model, all information on treatments is contained within-units. When some form of imbalance is introduced, due to, for example, dropout, the introduction of additional model

terms, or the use of an incomplete design, then some information on treatment effects will 'move' to the between-units stratum.

We are now in a position to consider the choice of fixed or random unit effects. The use of fixed unit effects, that is, treating the unit effects as any other linear-model parameter, means that all between-unit information is discarded. However, the resulting model is an example of a standard linear regression model and all the familiar regression procedures are available, including exact small sample *F*- and *t*-based inferences. Moreover, in such analyses, no assumption needs to be made about the distribution of the unit effects implying an additional degree of robustness in these analyses. They can be seen as crossover versions of conventional randomized block analyses in which units are blocks. There are many advantages to keeping the crossover analysis within this framework, not least the simplicity. So this should be considered the approach of first choice, provided it is appropriate, that is, when there is negligible between-unit information. In contrast, the use of random unit effects allows the recovery of the between-unit information, but this moves the analysis framework to that of the linear mixed model. This is less robust that the fixed effects model, because of the need to assume some distribution for the unit effects and, in addition, because small-sample inferences must rely on approximate methods (Kenward and Roger, 1997; Skene and Kenward, 2010). Hence this approach should be used only when strictly necessary, that is, when there is nonnegligible between-unit information is available for recovery, with sufficiently large-sample sizes. For the reasons given above, this will not be the case in the typical efficient, complete, crossover design with high within-unit correlation. Hence, careful consideration needs to be given to the data, design, and analysis model, before choosing the random unit effects approach. In specific settings, this approach has benefits, but these tend, in practice, to be the minority.

Another important distinction arises between the use of fixed and random effects when baselines are incorporated into the analysis. It is shown in Kenward and Roger (2010) that if random unit effects are used, then to avoid the so-called cross-level bias, an additional covariate must be included that consists of the sum of the baselines over all periods. With fixed unit effects, this is unnecessary.

Similar issues apply for discrete data, with some important distinctions. First, asymptotic arguments become the norm with the discrete data analogues of these analyses. This implies, among other things, that the fixed unit model cannot be used in the same way as above, by simply estimating an effect for each unit. Instead, the so-called conditional likelihood analyses are the proper analogues of these and are available only for certain models, namely logistic regression for a binary outcome, multivariate logistic regression for a nominal outcome, and log-linear regression for a Poisson (count) outcome (Jones and Kenward, 2014: Sections 6.2, 6.4, and 6.5.1, respectively). There is no conditional likelihood analogy for a proportional odds model for an ordinal outcome. Random effects models can be used however with all such classes.

A second important distinction concerns the variety of classes of model available for nonnormal outcomes, in contrast to the almost automatic use of the linear regression basis of models for continuous data. This is largely a consequence of the nonlinearity in the link between the model effects such as treatment and period and the mean outcome, which is necessary in such nonnormal settings. The distinction between two important classes of model, the so-called marginal and unit-specific, is especially relevant in the repeated measures setting and needs to be fully appreciated when analyzing discrete crossover data. These classes are discussed in the crossover setting in Jones and Kenward (2014: Chapter 6) and in a more general repeated measures setting in Molenberghs and Verbeke (2005). A brief consideration other types of outcome, such as event time, is given in Jones and Kenward (2014: Section 6.5).

Cross-Sectional Methodologies in Developmental Psychology

Abstract

Cross-sectional methodologies are typically adopted in the field of developmental psychology when assessing the impact of developmental age or stage on some cognitive measure. Here, we describe the statistical techniques that form the foundation of cross-sectional studies and illustrate their use through recent examples from the literature. We present both behavioral and brain-imaging work and emphasize the value of cross-sectional designs, with particular reference to studies that explore atypical development and consider change across the life span.

Introduction

A *cross-sectional* experimental design is one that involves taking a snapshot of information at a given point in time. In the context of developmental psychology, this broad approach is typically utilized to assess a cross-section of development, with a variable of interest being studied in children at different ages. For example, a study might measure how children's ability to perform on a memory task varies according to age, while keeping other factors such as socioeconomic status (SES) as consistent as possible. Although usually a design might examine performance across age, it could be across any continuous variable (height, intelligence, or time of day). For example, the measurement of interest could be performance on the memory task as it varies by SES, while age is kept consistent. However, generally speaking, cross-sectional designs in this branch of psychology refer to studies that take age or stage of development to be the continuously varying, predictor measure. In this chapter, we outline the statistical basis and value of cross-sectional designs for developmental psychology, and draw out the limitations and challenges inherent in them. We take specific examples from recent research in the field to illustrate the methodology, each of which takes data collected at a single point in time to understand the processes of change in cognitive systems.

The first systematic analysis of cognitive development arguably came not long after the advent of experimental psychology, when Alfred Binet attempted to measure average cognitive functioning in the domains of sensorimotor processing, language, memory, and logic in children between 6 and 15 years of age. This work resulted in the publication of the first intelligence test in 1905 (Binet and Simon, 1905), and is an excellent example of the early adoption of a cross-sectional methodology. Developmental psychology as a field in its own right did not really gather pace, however, until Jean Piaget's work from the 1930s onward. Piaget made intricate observations of his own children and used them as a basis for his hypothesis that cognitive development is staged and hierarchical (e.g., see Piaget, 1936). His work sparked an explosion of studies addressing cognitive development and, in particular, the underlying mechanisms of change. Developmental psychology is increasingly now thought of as the study of change in cognitive systems, regardless of age; development is a lifelong process.

Variation over developmental time can be recorded in one of two ways: either by studying individuals at different stages of development at one point in time, as discussed here, or by following the same set of individuals over multiple points in time. This latter, longitudinal approach is discussed elsewhere in the current volume. The establishment of statistical measures such as correlation and linear regression, based on the influential work of Karl Pearson at the turn of the twentieth century (see Pearson, 1896), allowed for the formalization of theoretical notions of development. Indeed, theory has driven, and has been driven by, the advance of statistical methods in every area of psychology. Taking once more the example of intelligence research, the establishment of modern notions of the structure of cognition went hand in hand with the development of the statistical technique of factor analysis (see Spearman, 1904). In the remainder of this article, we discuss the statistical measures that have been developed in parallel with the theory and practice of cross-sectional designs in developmental psychology. The addition of each statistical technique will allow us to elaborate from the basic concept of cross-sectional studies to a more complex and powerful set of methodologies. We begin with the roles of correlation and regression.

Correlation

Correlation describes the strength and direction of linear dependence between two variables. The statistic used to describe the relationship is most typically Pearson's r, which is a measure of the covariance of the two variables divided by the product of their standard deviation. The obtained value ranges from -1.0 to 1.0, from a perfect negative correlation, through no dependence between the variables, to a perfect positive correlation. As a measure of the strength of a relationship, r is used as an effect size. With respect to developmental psychology, correlations are frequently used to analyze the relationship either between age and performance on a cognitive measure, or between two cognitive measures at different ages. Cross-sectional designs lend

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23235-2

themselves well to correlational analysis as the predictor variable tends to be continuous and have a wide range. Here, we will explore some of the applications of correlational analyses in developmental psychology in the context of the relationship between month of birth and academic performance.

Throughout primary and secondary school, there is a significant correlation between children's performance on formal academic tests and their month of birth. This relationship has been established by running cross-sectional studies looking at the outcomes of national curriculum tests sat at ages 7, 11, 14, and 16 in the United Kingdom (e.g., Crawford et al., 2010). Children who are born at the end of the academic year tend to have lower educational attainment than children born at the start of the academic year. Equivalent relationships have been repeatedly found around the world, including in the United States (Elder and Lubotsky, 2008). Month of birth therefore has long-term implications for children's academic achievement and life outcomes as, among other things, it impacts who is likely to finish school and thereby find employment. Readers interested in the details of this relationship and what drives it are directed to Crawford et al. (2013); here, we use it to demonstrate some of the key principles of correlation.

A correlational analysis allows us to probe the nature of the relationship between month of birth and academic achievement. One important question is which aspect of month of birth drives, or mediates, the relationship. The two prime candidate factors are age at starting school and age at which the tests are sat. As these two factors are themselves not perfectly correlated in the United Kingdom, Crawford and colleagues (Crawford et al., 2010) were able to separate out the impact of each. By controlling for each in turn, the authors found that the relationship between month of birth and academic test score is largely driven by, or mediated by, the age at which the test is sat. For the conditions for mediation, see Baron and Kenny (1986) and Holmbeck (1997). Another question that can be answered through a correlational analysis is whether variables exist that impact, or moderate, the strength of the correlation under investigation. In the case presented here, multiple factors could theoretically be moderators. For example, the relationship might ameliorate as children get older, such that age acts as a moderator. In actual fact, the effect of month of birth on academic achievement does lessen over time, but it remains statistically significant to the point of college entry. One paper has found that gender is another moderating variable, with exam results at age 16 from children in the United Kingdom showing that boys born in the summer had the greatest disadvantage and girls in the autumn the greatest advantage (Sharp, 1995).

Correlation, then, can be a powerful tool to establish a relationship between two variables. This method of analysis does have considerable limitations, however, including the assumption of linearity (for nonlinear relationships, growth-curve modeling is more suitable). What correlation cannot tell us is whether the relationship between two variables is causal. This is a difficult problem to overcome without either a longitudinal data set to run time-lagged correlations, longitudinal regression, or the experimental manipulation of variables.

Regression

Simple regression determines the extent to which a value of the dependent (outcome) variable can be predicted based on the predictor variable. This technique differs from correlation in that it tacitly assumes a directional causal relationship between the predictor and outcome variable. The distinction is perhaps clearest when age and cognitive task performance are considered: increasing age indirectly leads to improvements on cognitive tasks, but improvements on cognitive tasks cannot lead to augmentation of age. It is worth noting that changes in chronological age do not directly cause improvements in task performance; age is associated with maturation and experience-dependent learning, which, as aspects of cognitive development per se, may be considered more legitimate direct causes of task performance improvement.

It is common for researchers to use performance on one task to predict performance on another. Note that, according to the logic discussed here, such researchers are tacitly stating that the predictor variable causally determines the outcome variable to an extent. For example, Purser et al. (2012) investigated whether measures of components of Baddeley's (1986) model of working memory predicted the route-learning ability (acquiring knowledge about routes through space) of typically developing children aged 5–11 years. Baddeley's model features both verbal and visuospatial short-term storage components, and a 'central executive' that is concerned with controlling attention (among other things). Verbal short-term memory was assessed with digit span, a task in which participants must repeat back a list of spoken numbers in serial order; visuospatial short-term memory was indexed by Corsi span (Corsi, 1972), in which the participant attempts to reproduce a sequence of spatial locations. The 'executive' component was measured with the Go/No Go task, in which a pseudo-random series of differently colored circles is presented on a computer; participants must press a key as quickly as possible on seeing each circle, unless it is red, in which case they should refrain from pressing the key. Route learning was assessed by the number of errors made in the course of learning a route through a virtual environment maze.

A series of linear regressions indicated that the measures of all three model components – verbal and visuospatial short-term memory and the central executive – were statistically significant predictors of children's route-learning ability. However, one would expect every cognitive function tested to improve with age in this cross-sectional sample and hence be intercorrelated, which was indeed the case. Stepwise multiple regression was therefore used to investigate the independent contributions of each cognitive component to children's route learning.

In forward stepwise multiple regression, predictors are added one by one to the regression model. Due to the fact that multiple regression tests for the unique variance in an outcome variable explained by each predictor, it is important to enter predictor variables in a theory-sensitive manner for this kind of analysis. Both memory tasks must have involved some degree of attentional control, because the stimuli could not be recalled if they were not attended to. The executive task, however, had no clear short-term storage demands. Therefore, the executive task was entered as the first predictor, accounting for

a significant proportion of variance in route learning (40%). Neither of the storage tasks contributed significant additional predictive power, suggesting that their predictive relationships with route learning, as discussed in this section, were mediated by the executive control demands of the tasks.

Despite the tacit assumptions made when using regression, it is actually very hard to establish causality. The oft-used phrase 'correlation does not equal causation' should be extended to 'neither correlation nor regression equals causation.' Using a regression model presupposes a causal relationship between the predictor and the outcome variable, but it cannot establish it. Longitudinal methods are better suited to test such hypotheses.

Matching

Matching is the equating of groups on some variable – usually chronological or mental age – to afford a meaningful comparison. It is frequently utilized in developmental disorder research, whether cross-sectional or longitudinal, with the aim of discovering whether a group with a disorder is above or below the level of task performance expected for their age or for their ability in some domain(s). The control group, then, acts a reference point for the disorder group, in order to rule out candidate explanations for any resulting group differences. Matching has become controversial, due to the fact that it ignores variability in the matching variable and is not developmental in its emphasis (see Thomas et al., 2009).

Figure 1 The task display showing examples of the paths in each condition of the experiment (the order of presentation is illustrated in the figure, but no digits were actually shown on the display; although path lengths were matched across conditions, a shorter Crossover path is shown for the sake of overall clarity).

The implicit logic behind group matching, noted by Jarrold and Brock (2004), is that matching will equate for 'noncentral' task demands: understanding instructions, controlling response behavior, selecting and using appropriate strategies, and so on. However, the mental age measures most commonly used for matching are very indirect means of achieving this: the Peabody Picture Vocabulary Test (PPVT; Dunn and Dunn, 1997) and Raven's Colored Progressive Matrices (RCPM; Raven et al., 1998) are measures of receptive vocabulary and nonverbal reasoning, respectively. Jarrold and Brock, instead, advocate control conditions that are essentially the same as the experimental task, differing only in that the target cognitive ability is not required for successful performance.

Purser (2006) investigated whether individuals with Down syndrome (DS) rely on a visual strategy to support their visuospatial short-term recall, relative to a typically developing control group. There were three conditions, presented on a honeycomb-like grid on a computer touchscreen: 'Normal' trials on which the path traced by the visuospatial sequence could be represented as a regular four-sided shape, 'Crossover' trials on which the path crossed over itself once, and 'Inline' trials on which the path fell on a single line, so that no two-dimensional shape could be represented (see **Figure 1**). The sequences were presented by circles momentarily changing color, after which the participant attempted to touch the circles in correct serial order.

Participants from DS and typically developing groups were matched on the Normal version of the task, ensuring that the two groups were matched for general factors related to successful task performance in the other two conditions. **Figure 2**a shows each group's average recall over the three conditions. The DS group was significantly poorer on the Inline version of the task than the TD group. An error analysis (**Figure 2**b) indicated that the DS group made more order errors than the TD group in both the Crossover and Inline conditions. These results indicated that the DS group found path crossing more detrimental to recall than the TD group,

Figure 2 (a) Condition effects by group in the visuospatial recall task. Vertical lines depict standard errors of the means. Maximum score = 16. TD = typically developing; DS = Down syndrome. (b) Condition effects by group for order errors in the recall task. Vertical lines depict standard errors of the means.

consistent with relying on a visual strategy. Importantly, due to the 'task-matching' method, these differences cannot be attributed to general factors differentially affecting the groups.

Trajectory Analyses

Trajectory analyses (Thomas et al., 2009) are essentially modified forms of analysis of variance (ANOVA). Instead of comparing group means, however, the analyses involve the comparison of regression lines, or 'developmental trajectories,' between groups, across conditions, or both. Trajectories are linear functions that vary in terms of both their gradients (rates of change) and intercepts (initial levels of performance).

Trajectories are generally used to relate task performance to either chronological or mental age; they are especially useful for investigating the developmental relations that exist within developmental disorders that show uneven cognitive profiles, or *developmental dissociations*. Although longitudinal methods would ideally be used for such investigations, the cross-sectional approach can give an approximation of developmental trajectories, which can subsequently be validated by longitudinal research.

Trajectories help to answer the question 'Do individuals with a disorder perform at an age-appropriate level?' In a simple example of the trajectories approach, Purser and colleagues (Purser et al., 2011) compared word knowledge and vocabulary age in the rare genetic disorder Williams syndrome (WS), and a typically developing (TD) control group. In individuals with Williams syndrome, language development can appear a relative strength, with language level exceeding overall mental age, but the exact nature of these language abilities has been the subject of much research. In Purser et al.'s study, word knowledge was assessed with a definitions task (in which participants are asked to define words; e.g., 'What is an elephant?'). Vocabulary age was assessed via the British Picture Vocabulary Scale (BPVS; Dunn et al., 1997). **Figure 3**a shows the two groups' performance on the definitions task: the WS group's performance began at a level appropriate for vocabulary age, but then the TD group improved at a faster rate than the WS group. The gradients of the trajectories differed but not the intercepts.

Participants also completed a categorization task, which was also a measure of word knowledge but avoided some of the metacognitive demands of the definitions task, such as understanding what a definition is and how to respond appropriately. In the categorization task (**Figure 3**b), the performances of both groups developed at similar rates, but the WS group was markedly poorer than the TD group, on average, than predicted by vocabulary age. Here, the gradients did not differ, but the intercepts did.

Taken together, these results indicated that individuals with WS have poorer word knowledge than predicted by their vocabulary age, but this word knowledge improves at a similar rate with increasing vocabulary age in both WS and typical development. The 'falling behind' of the WS group on the definitions task, relative to the TD group with advancing vocabulary age, was likely due to older TD children understanding the metacognitive aspects of the definitions task better than participants with WS of a similar vocabulary age.

Brain Imaging

Although all the data we have considered thus far have related to behavioral measures, researchers are increasingly turning to brain-imaging techniques such as functional and structural magnetic resonance imaging (MRI) (see Holland et al., 2007; Knickmeyer et al., 2008, for examples of functional and structural studies, respectively) and electroencephalography (EEG) (e.g., Thatcher et al., 2008) to inform developmental theory. Such techniques allow an examination of not just how behavior and cognition change over development, but also how the brain changes, and how the relationship between the brain and behavior may alter, too. Questions being addressed include the following: what are the typical functional relationships between different brain regions over development? How do functional brain activity and the structure of the brain relate to the development of specific skills over childhood, and indeed the lifespan? What can differences in the brain tell us about why behavior is atypical

Figure 3 (a) Mean number of features given by participants in the definitions task plotted against vocabulary age in years. (b) Mean number of correct categorizations plotted against verbal mental age in years. WS = Williams syndrome; TD = typically developing. Data from Purser, H.R.M., Thomas, M.S.C., Snoxall, S., Mareschal, D., Karmiloff-Smith, A., 2011. Definitions versus categorization: assessing the development of lexicosemantic knowledge in Williams syndrome. International Journal of Language & Communication Disorders 46 (3), 361–373.

in children with developmental disorders such as dyslexia? The questions addressed using brain imaging, and the data acquired, are complex and require careful thought during the design of studies and the interpretation of results. This is especially true in the light of the many-to-many relationships between brain and behavioral measures. Individual behaviors are generated by networks of brain regions working together, and an individual brain region may be involved in generating more than one behavior. Moreover, a developmental perspective must take into account that the experienced environment may continually change over the lifespan.

While adopting brain-imaging techniques permits some key insights into the development of cognition, using these techniques with children also raises practical and theoretical issues (see Davidson et al., 2003, for a discussion of the use of functional MRI (fMRI) techniques with children). The majority of cross-sectional studies in developmental psychology require a wide age range in order to capture change over development. This presents a challenge in that the paradigm must be suitable for a range of ages, and it must be sensitive enough to measure performance at each age. Being sensitive across the age range requires that no set of participants performs at either floor or ceiling on any task. With brain imaging, this challenge is compounded by changes in physical properties such as skull thickness and brain size, as well as the propensity for young children to move about during testing. All of these factors, and many more besides, influence the quality of the imaging signal and show both individual differences and age effects. Although these issues are always relevant when working with a developmental sample, they are easier to take into account if testing the same children repeatedly, that is, if using a longitudinal design. Nevertheless, cross-sectional studies of development involving brain imaging are relatively sparse from ages 2 to 6 years, where the practical challenges of obtaining measurement are most severe.

Cross-sectional techniques can be applied to any brain-imaging study, just as they can to any behavioral study. Here we take an example of a lifespan study, emphasizing that the study of developmental processes considers trajectories beyond the end of childhood. Richardson et al. (2010) gathered receptive vocabulary and nonverbal IQ scores for 47 individuals aged between 7 and 73. These participants were then scanned using MRI to look in detail at the structure of their brains while they rested. When the relationship between brain structure and performance on the behavioral measures was analyzed, a significant correlation between vocabulary score and gray matter density was revealed in both left posterior superior temporal sulcus and the left posterior temporal–parietal junction. In the teenage participants alone, an additional correlation was discovered between vocabulary score and gray matter density in the left posterior supramarginal gyrus. When Richardson et al. examined which of these regions were activated more during auditory and visual language comprehension than control tasks, only the first two regions showed significant effects. What, then, is the function of the left posterior supramarginal gyrus, where more gray matter was observed in teenagers with higher vocabulary abilities? The authors suggested that the developmental shift in the relationship between brain structure and behavior was driven by the way in which vocabulary is learned during the teenage years; specifically, that the relationship seen in teenagers is driven by the learning style of explicit instruction through lexical or conceptual equivalents common in secondary school, as distinct from incidental vocabulary learning through interaction that is more typical in younger children and adults.

In many ways, brain imaging lends itself as well to cross-sectional designs as do behavioral measures, but it provides an extra level of understanding and complexity that offers insights different to, and arguably beyond, behavioral measures. However, the difficulties inherent to all developmental studies can be exaggerated by the demands of adopting complex imaging techniques.

Benefits and Limitations

The major benefits of cross-sectional techniques in developmental psychology are practical in nature. The first benefit is that cross-sectional work is relatively inexpensive. The usual aim of cross-sectional studies is to get a measure of change with development, which may also be achieved by repeatedly testing the same children over time rather than testing children of different ages at one point. Such longitudinal studies require repeated testing over many years, resulting in high staff and laboratory costs, a significant commitment from participants, and the risk of data loss where that commitment cannot be delivered. The second benefit relates to the difficulty of selection bias, which is common to almost all psychology experiments. Researchers often invite participants who are close by, accessible, and likely to comply with studies. In addition, people who are proactive and interested in psychology are much more likely to take up invitations or get in touch with labs. This has some serious implications for the whole field (see Jones, 2010, for a discussion of the impact of overusing certain demographics in psychology studies). A specific problem for longitudinal studies is that people drop out over time, so for some participants a researcher might have just one data point, while for others they have several. Unfortunately, who stays in the study and who drops out are often not random. Participants might drop out because they find the study challenging, or perhaps because of difficulties with travel or unemployment. This means not only that data sets are often incomplete, but also that the data that are available are particularly prone to selection bias. Cross-sectional studies avoid at least some of this difficulty.

Despite the clear benefits of adopting a cross-sectional approach when running a developmental study, there are equally a number of important limitations. Perhaps the primary limitation is that when looking for the effect of age on some cognitive measure with a cross-section of children, there is an inevitable confound of individual differences. Do these children differ on the task because one is older or as a result of some other variable, such as nonverbal IQ or attentional control, which has not been measured? This will manifest as 'error' in the statistical models used, reducing the ability to find effects of interest in the variables that have been measured. In contrast, longitudinal methods effectively control for many of these unmeasured variables, to the extent that they are stable across the time points of measurement involved in the study.

The second major challenge of cross-sectional methods is the development of an appropriate paradigm (as briefly discussed in this article). Cross-sectional methods assume that the cognitive function in question is captured in the same way across the whole range of chronological or mental ages considered. However, it is not always clear that this is, in fact, the case. There are two main situations in which the assumption may not be met. The first is when different tasks are used for participants of different ages or ability levels. Consider how one might test the language ability of an 18-month-old, a 5-year-old, and a 15-year-old. The first might rely on a parental questionnaire of the vocabulary that the child produces; the second can focus on more directly on the child's language skills in the oral domain, including both vocabulary and syntax; and the third may assess more complex aspects of, say, syntax or pragmatics in the written domain. However, the problem of using different tasks at different ages is obvious: if the task is different, then the demands must be different. This creates problems of interpretation because these differences in task demands may lead to differences in scores across the range of ages measured, rather than (or in addition to) any underlying differences in the target cognitive function.

A more basic problem is that the different tasks may be scored in different ways. For example, the RCPM (Raven et al., 1998) is a test of nonverbal reasoning for children and is scored out of 36 items. Raven's Standard Progressive Matrices (RSPM; Raven et al., 2003) is a broad equivalent for adults and is scored out of 60. How should one compare scores from each test? In this case, there is a solution, because norms are available that indicate what score the norming samples achieved on average across the whole age range, with standard deviations for each age. For a given age, participants' score can be converted into how many standard deviations they scored above or below the norm average. When such norms are not available, researchers can standardize scores against their own sample, although large numbers are generally required.

A subtler situation arises when the task used does not change but the determinants of task performance do. A clear example is the decline in working memory capacity observed in older adults. According to Baddeley's (1986) model of working memory, there is an attentional control component, the 'central executive,' and two 'slave' passive storage systems, the phonological loop and visuospatial sketchpad, which temporarily hold verbal and visuospatial representations, respectively. Older adults perform similarly to younger adults on tasks that require few executive demands (i.e., they require little attentional control), but are poorer than younger adults on tasks that do make such demands (e.g., Craik and Byrd, 1982). Thus, the poorer working memory scores of older adults reflect limitations of attentional control, but not of working memory per se.

In order to conduct valid research comparing task performance across the lifespan, researchers must analyze their main task in terms of the cognitive demands that it makes. If there is reason to believe that any of these demands, other than the target cognitive function, might change across the chronological or mental age range involved in the research, then these component demands should be independently measured so that any observed differences in the main task can be confidently attributed to the target ability rather than to the secondary demands.

A final limitation is the widespread use of linear modeling in cross-sectional studies of development. Although some cognitive changes may approximate straight lines, many may not. However, although some challenges in interpretation may arise, most linear methods, including trajectory analyses, can be adapted to nonlinear models simply by altering the model options in the statistical software used (see Thomas et al., 2009). As noted by Thomas and colleagues, the principle of parsimony may be invoked when deciding whether a linear or nonlinear model is preferable: nonlinear models involve a greater number of parameters than linear models.

Getting the most out of cross-sectional methodologies will mean taking advantage of the benefits and minimizing the impact of the limitations. Ways of minimizing the impact of the limitations might include taking care to abate potentially confounding factors where possible, and keeping response demands simple for all paradigms, while ensuring as wide a performance range as possible; using adaptive tasks is one way to achieve this.

Conclusion

The aim of this article was to describe the use of cross-sectional methodologies in developmental psychology, and to explain their origin, their strengths, and their weaknesses. We have discussed the theory behind the statistical techniques adopted in cross-sectional studies and used examples from the literature to illustrate their use.

Cross-sectional methodologies provide substantial scope for the development of highly informative studies without the cost associated with longitudinal work. The development of trajectory modeling allows a developmental perspective to be taken, at the heart of which is the aim of determining the mechanisms of change in cognitive systems. Throughout the history of developmental psychology, the establishment of statistical methods such as regression has been intimately tied up with theoretical advancements and new conceptual understanding. This is certainly apparent with respect to cross-sectional studies, although equally the statistical limitations inherent in data collection at a single point in time must be borne in mind. Development is, in its most fundamental sense, a dynamic process of change. Indeed, the word itself comes from the French *développer*, to unfold. Research into the process of cognitive development must, therefore, balance practicality with the theoretical rigor of longitudinal studies.

The future of cross-sectional methodologies lies in researchers pushing the boundaries of what questions can be asked: using trajectory analyses to trace the patterns of cognitive change, using brain-imaging techniques to answer questions about the neuroanatomical and neurophysiological underpinnings of cognition, and bearing in mind that developmental psychology is not just about cognitive development in children but also about change throughout the lifespan.

Crowds in History

Abstract

Crowds continue to play a major role in politics and society, just as they have done since the first forms of urban living were established in ancient times (although they can also be found as forms of protest in agricultural societies). As such the issue of crowds and how they behave is a significant area of research. This article outlines the 'Roman school' of mass psychology around 1900 (LeBon), the social–historical school of French Revolution research (Lefebvre), the modern classic 'history from below' approach (George Rudé et al.), and the quantitative American school of historical sociology (Charles Tilly). The claim has often been made that crowd rebellions can normally be reduced to two main essentials: 'subsistence' and 'liberties.' More recent research, joining the modern classic school, has increasingly included other aspects of crowds that have been too neglected, including violent actions against religious or ethnic minorities.

After stating the historical relevance of crowds, they are defined as relatively sudden gatherings of large groups of people whose actions are goal oriented and conflictual. They interrupt the regular course of everyday life and disturb, or threaten to disturb, public order. Crowd history has primarily been indebted to the social–history paradigm, ranging methodologically from 'thick description' to extended protest statistics. Central questions concern times and places of crowds, their physical composition, forms, and motives of action, their targets, the role of peacekeepers and governments, and their long-term effects on high politics and society. Describing different schools, four crucial phases are identified: the 'Roman school' of mass psychology around 1900 (LeBon), the social–historical school of French Revolution research (Lefebvre), the modern classic 'history from below' (Rudé et al.), and the quantitative American school of historical sociology (Tilly). Focusing on early-modern Europe, the modern classic school reconstructed a peculiar repertoire of crowd actions. At the center were food riots, a long lasting European conflict on values and goals that is best explained by Thompson's path-breaking concept of the moral economy. Taking the whole spectrum of crowd actions together, their unwritten program can be reduced to two main essentials: 'subsistence' and 'liberties.' These issues were defended in a specific mode of popular 'rebellious traditionalism' against the two great dynamic powers of expanding markets and national states. More recent research, joining the modern classic school, has increasingly included other aspects of crowds that have been too neglected: violent actions against religious or ethnic minorities (especially anti-Jewish riots), monarchistic, and conservative crowds within dynastic ceremonies or national movements, or twentieth-century crowds in 'street politics' and party political action. There has also been a broadening of perspectives on non-European crowds, such as peasant resistance in Asia or historical food rioting in China or India, and very recent conflicts in Africa and Latin America. The long lasting interpretive struggle (*Deutungskampf*) on crowds is marked by a double disappointment: neither have crowds turned out to be the great culture-destroying evil, nor have they fulfilled any 'higher' historical missions. However, a certain ambivalence remains: although emancipating aspects may dominate, in their repertoires there were (and are) also dangerous exclusionary efforts and violence. But following their unwritten program of 'subsistence' and 'liberties' in the main, crowds – as paradoxical as it may seem – were indirect reformers, cowriting the present day agenda of social and political human rights. There has been some transformation of crowds in Western societies: they have become normal parts of political culture. Social- and political-egalitarian demands have been shrinking for some time now, ranking beside (or behind) new values and demands within 'new social movements.' Becoming less class specific, crowds today no longer consist exclusively of the lower orders, but are more likely to be mixed. As an elementary form of face-to-face public, crowds continue to persist in the age of mass media.

Crowds do play an important role in history. Particularly during times of crisis and revolution, they can function as prime movers in historical–political conflicts. As a constituent feature of everyday public life, the omnipresent crowd is a highly complex phenomenon, especially in modern urbanized societies. In view of the innumerable forms that crowds take, in the most varied of contexts, for pragmatic reasons it is sensible to distinguish between: (1) more trivial everyday crowds as well as crowds of a recurring, institutionalized, and routine nature; and (2) exceptional, unforeseeable crowd events.

For research purposes, crowds can be defined as relatively short-term gatherings of large groups of people (on streets or squares or in the countryside – in any event, in the open air), whose actions are goal oriented and, as a rule, conflictual. Crowds are assemblages that interrupt the regular course of everyday life and disturb the public order, or at least threaten to disturb it. Under certain circumstances, of course, an everyday or routine crowd can also transform itself into one that will be conflictual.

Crowd history was (and will likely remain) primarily indebted to the social–history paradigm: theory oriented, but seldom fixated on theory – in fact, with a fair bit of skepticism regarding theory; and utilizing a variety of empirical methods, singularly or in combination, from 'thick description' to

extensive statistics on protest. Central concerns are the precise reconstruction of crowd events, the involved groups and their identities, and a microhistorical embedding in local contexts. Dominating questions concern exact times, size, duration, frequency, and topography or geography of crowds. Research topics are their physical composition (social status, ethnic identity, religion, age, sex) and the – considerably heterogeneous – behavior of individuals or smaller groupings in these events.

Other focuses are the forms and motives of action (violent tendencies, emotionality, resentment, mentalities, visions), in addition to occasions and possible structural reasons for common action. Furthermore, crowd history investigates the targets of crowd action, as well as the presence and function of peacekeepers in such confrontations. And last but not least, crowd history discusses the results and long-term consequences of crowd events in consideration of high politics and society.

Phases and Schools: Changing Images of Crowds

Academic crowd research was first begun toward the end of the nineteenth century, and its beginnings are conspicuously multidisciplinary: philosophy, psychology, criminology, sociology, and anthropology occupied themselves with the phenomenon; only gradually did historical studies turn their attention to the subject. Against the background of opposing political–ideological positions, several academic schools disputed the 'true essence' or the 'actual character' of crowds. Depending on one's position, interpretations ranged from an extreme damning of crowds as purely negative and regressive destroyers of civilization, to their enjoying an idealized historical–philosophical role as genuine creative agents, as essential driving forces of historical progress. From the historian's perspective, there are at least four important phases.

The starting point was the so-called 'Latin School' of mass psychology around 1900, represented by such authors as the Italian criminologist Scipio Sighele (*La Folla Delinquente*, 1891), the French popular scientist Gustave LeBon (*La Psychologie des Foules*, 1895), and the French criminologist and sociologist Gabriel Tarde (*L'Opinion et la Foule*, 1901). Relying for their historical evidence primarily on one-sided studies of the French Revolution by the conservative historian and philosopher Hippolyte Taine, their speculative theories concerning crowds were a projection of bourgeois-conservative fears of social subversion at the *fin de siècle*: "Their crowds loomed as violent, bestial, insane, capricious beings whose comportment resembled that of mentally ill, women, alcoholics, or savages" (Barrows, 1981: p. 5).

The emerging social–historical school of French Revolution research opposed the conservative LeBon mass psychology by de-demonizing the crowd debate through empirical case studies addressing the character and role of crowds during the French Revolution. One of this school's path-breaking authors was Georges Lefebvre. In *La Grande Peur* (1932) and especially in *Foules Révolutionnaires* (1934), he showed how rebellious groupings were stimulated through various types of oral communication (e.g., spreading of rumors, suspicions, and mental images), and how the *foules pures* of everyday life transmogrified into the *foules révolutionnaires* when seized by a 'collective mentality.'

After the World War II, a modern classic school of crowd research was constituted that traced its ancestry partly to the social–historical school of French Revolution research. The classic school's first important propagator was an occasional student of Lefebvre's, George Rudé, whose 1950 doctoral dissertation treated the Paris workers and their uprisings of 1789–91. In his studies on crowds in the French Revolution and on crowds generally in France and England from 1730 to 1848 (Rudé, 1964), he identified for the first time the 'faces in the crowd.' Together with Eric J. Hobsbawm's early studies of the pre- and early-industrial workers groups whose rebellious behavior was plausibly labeled 'collective bargaining by riot' (Hobsbawm, 1952), as well as the related work of Edward P. Thompson, especially his paradigmatic study of *The Moral Economy of the English Crowd in the Eighteenth Century* (Thompson, 1971), the classical canon of a new history from below emerged. These historians understood themselves to be an open and undogmatic variant of a Marxist historiography of the West. At first an oppositional subdiscipline, from the 1960s to the 1990s it quickly gained a wide reputation in academic circles, inspiring numerous other studies.

There was a parallel development in the American social sciences, using modernization theory and quantitative measurements in historical–sociological research on crowds. Crucial was a more systematic investigation of possible causal connections between large processes, such as industrialization, urbanization, or social crises, and the frequency and geography of crowd occurrences. In a critical test of theory, then-current concepts of collective behavior and of social movement research (relative deprivation, among others) were checked against historical evidence. This led to more refined methods of crowd event analysis, accumulating more precise protest statistics over longer periods and/or testing its geographic diffusion for strategically chosen regions. Exemplary is the work of Tilly et al., in particular the comparative study of France, Italy, and Germany in *The Rebellious Century* (1975), or the strictly quantitative and simultaneously Thompsonian case study of English riots 1790–1810 (Bohstedt, 1983).

The Unwritten Program: 'Subsistence' and 'Liberties'

For the longest time, European societies of the early-modern period, including the nineteenth century, figured as the classic time frame for the bulk of crowd research. The essential scope of crowd activities was above all defined by the secular processes of state centralization and national state-building, the expansion of market economies, social polarization, and proletarianization. Viewed from the lower-class angle, one is able to speak of a European age of persistent material shortages. Under conditions of subjection and/or political immaturity, the lower classes found themselves in permanent conflict with authorities and social elites for subsistence guarantees, communal rights and freedoms, and cultural autonomy.

Rudé's and Hobsbawm's 'new picture of the crowd' was and remains largely a counterimage to the previously dominant

LeBon tradition. Crowds, it was now shown, were not – as a rule – criminal rabble but people of established residence, average working men and women, poor but orderly folk. Their motivations were a frequent mixture of Jacobin egalitarianism and conservative monarchism. Their collective behavior was one of direct action, and they pursued their thoroughly rational goals with fitting means, this sometimes translating into violence. However, it is said that their violence was predominantly symbolic and a question of efficacy. Moreover, their successes were of limited nature, particularly as their actions were so short lived and lacking of far-reaching visions. Thus, conflict crowds were to be considered forerunners of later social and political movements with lasting organizational structures and long-term social–political programs.

These and related studies established a solid canon of conflicting crowds, a European repertoire of riots. These included: peasant uprisings against noble estates, antitax protests against mounting state prerogatives, religious riots between competing confessions, subsistence-based actions of the rural and urban lower classes, moral rebukes in the tradition of *charivari* (rough music), strikes and boycotts of artisans and workers, machine-wrecking, but also aggressive acts of popular monarchic loyalty against alleged enemies of king and church, and xenophobic outbursts against 'strangers.' As the latest research for the UK, France, and Germany has shown, in no other early-modern conflict of any duration were crowds so involved as in food riots.

More than 3000 food riots have been documented for France between 1560 and 1860. At their center were the blockades of interregional grain trade to prevent scarce resources from leaving their place of origin. Participating in these blockades were mainly the rural and urban lower classes from the highly commercialized farming regions of the far-reaching agrarian hinterlands of Paris. For four decades, ever since 1760, the power struggle over access to limited food resources became permanent in France. The attempt of Controller General Turgot in the fall of 1774 to deregulate the national grain trade according to physiocratic liberal doctrines, ended in the fiasco of the Guerre des Farines (Flour War) of 1775, when over 300 food rebellions forced the government to back down its policy (Bouton, 1993).

There have been about 1000 food riots documented for England in the period 1530–1820, the majority of them taking place in the last 80 years of that time span. With regard to the years around 1800, Bohstedt speaks of a communally anchored 'protocol of riot,' of 'orderly disorders,' with widely accepted public rules for all of the participants. With crowd action as an essential element of community politics, poorer consumer groups, especially in small and medium-sized market towns, participated successfully in the creation of reasonably tolerable living conditions (Bohstedt, 1983).

For German regions (1700–1870) over 400 food conflicts have been substantiated. They culminated in the 1840s (shortly before and during the Revolution of 1848), a decade that has been characterized as the 'angry forties.' Particularly in Prussia's East-Elbian provinces, the eighteenth-century myth of a paternalistic 'social monarchy' quickly faded. Market-driven resource scarcities, not least the result of agricultural exports to Western Europe, forced a sharp internal 'dissent about markets.' Even more so than the urban lower classes, the rural poor frequently saw themselves robbed of whole food entitlements (Gailus, 1990).

All in all, these recurring pre- and early-industrial mass conflicts attested to not only a simple struggle for calories among the abject poor and hungry, but symbolized a central conflict of values and goals. On the one side were liberal principles and Utopias envisioning abundant markets and property for all, while opposed to it were nontransferable subsistence rights and the blows to the human dignity of rapidly expanding market-dependent classes in an increasingly urbanizing market society.

Probably no other model has so persuasively explained the social and cultural meaning of pre- and early-industrial crowd activities as Edward P. Thompson's classic notion of moral economy, which he developed through an analysis of the rebellious behavior of the working poor in eighteenth-century England. According to his study, the customs and rituals practiced by the crowds in their numerous food riots, their angry outbursts and anxious visions, their claims and demands, were embedded in "a popular consensus as to what were legitimate and what were illegitimate practices in marketing, milling, baking, etc. This [consensus] in its turn was grounded upon a consistent traditional view of social norms and obligations, of the proper economic functions of several parties within the community" (Thompson, 1971: p. 79). For Thompson the word 'riot' is too narrow a concept to adequately describe all the issues at stake in these confrontations. In order to assure their 'way of survival,' crowds (or people) were in permanent collective negotiations with aristocracy and gentry, with officials and the middle classes. The crowds would typically remind the authorities of their traditional paternalistic duties vis-à-vis the weaker members of the community. In the ritualized forms of conflict with ruling elites, in expressive and symbolic confrontations of political 'theater' and 'counter-theater,' they actively participated in the social organization of their own living conditions and thus functioned as an influential collective subject. Crowds were exercising direct influence on the epoch's balance of power, which was shaped by the political hegemony of the gentry (Thompson, 1991). One can with good reason speak of 'participation by riot' or of popular 'participation before participation.' Despite some critical objections, the moral economy model has asserted itself as the most successful interpretive concept for historical studies of conflict crowds – and not solely for food riots and for European conflict patterns. More recent work attests to its yet fertile analytic potential (Randall and Charlesworth, 1996).

Focusing the implications of these old European crowds on a few essential aspects would above all include 'subsistence' (entitlements to food, rights of social share) and 'liberties' (in the sense of additional rights and popular customs). This collective establishing of values was both asserted and defended against outside 'disturbances' and all actual and imagined threats to existence through dynamic penetration of the two great powers, the national state and the expanding modern market. This culture of resistance of conflicting crowds has contributed in manifold ways to the formation of basic political and social rights of modern constitutional states.

Conceptual Constrictions – Widening of Perspectives

The advance of the modern social–historical school (1960–90) had a lasting effect on the historical image of crowds: the 'bad crowds' of the older conservative orthodoxy turned into the 'good crowds,' possessing a predominantly positive, emancipating function. However, completely or partially obscured were other aspects of crowd history: aggressive, conservative, and nationalistic or chauvinistic mass events, as well as excessively violent and ethnically motivated outbursts. Also criticized has been crowd history's exclusive concentration on rebellious crowds. Too little attention has been given to other forms of nonconflicting crowds. In addition, the 'great watershed' of 1850, allegedly occasioning a transformation of crowds, has hardly been proven. Despite a sneaking institutionalization of crowds over the following decades, they have remained critically important in the industrial societies of the late nineteenth and twentieth centuries (Holton, 1978; Harrison, 1988).

Crowd history has to pay more attention to violent actions against minorities and outsiders. Excessive crowd violence was mostly reserved for pogrom-like persecutions of the Jewish minorities. These assumed an almost nationwide character at least twice in nineteenth-century Germany: in the form of 'Hep-hep riots' (1819) against the political emancipation of the Jews, and the forcible expulsion of south German village Jews within the wider context of the rural mass movements of the 1848 revolutions (Rohrbacher, 1993). As of the second half of the nineteenth century, pogroms established themselves in eastern Europe with much greater militancy – in Russia, especially the Ukraine, and in parts of Poland – its chief phases encompassing the periods 1881–84, 1903–06, and 1919–21. Until the end of the nineteenth century these actions were perpetrated by crowds of similar compositions to those in other riots (Klier and Lambroza, 1992).

There has been an increasing shift of focus to nonconflicting crowds, a development promising to greatly expand the field of research. Dynastic governmental ceremonies, middle-class-inspired national festivals, traditional celebrations, religious feast days, and new style leisure activities could easily assume the form of mass events, though in different guises and in radically transformed public functions: staged by the ruling class and social elites and hierarchically structured; composed of a mixture of social groups, neither exclusively nor primarily from the lower classes; symbolically strengthening the existing rule and its established social order, as opposed to rebellious behavior protesting destitution and political impotence; in their effects, socially integrative rather than polarizing. The lower classes, usually self-determining actors at the very nucleus of crowd activities, figured here primarily as public, as mere backdrop.

A study of Bristol 1790–1835 shows that next to peaceful 'election crowds,' 'royal and military crowds,' and 'recreational crowds,' unruly 'crowd riots' were among those events occurring with the highest frequency in the city. However, at the same time, 'crowd riots' formed only a minority (22%) of a sample that covered all types of crowd occurrences taking place within the city. The local elites of Bristol had ample skill and experience in successfully mobilizing large crowds onto the main streets and squares for purposes of their own (Harrison, 1988).

The general European 'nationalization of the masses' in the nineteenth century included a wealth of identity-forming national celebrations and mass manifestations.

A comparative study of middle-class movements for national memorials in France and Germany has demonstrated the precarious and paradoxical strategy of including the lower classes in the mythical 'nation,' while simultaneously drawing sharp social distinctions over and against these very same lower classes. It was above all through the militarization of the bourgeois festival culture that the elites were able to overcome their deep-rooted fear of the masses (Tacke, 1995).

Expanded political participation, as well as transformations within the public sphere in industrial and postindustrial societies of the twentieth century in no way contributed – as often asserted – to the disappearance of protesting crowds. Rather, one can speak of modifications, and of coexistence of direct action with newly learned and more organized and representative political forms. After 1850, aside from periodic recurrences of crowd activity in line with the older model (for example, food riots in France, and especially in Italy and Spain), one finds numerous newly invented forms of crowd action, above all strikes, boycotts, mass manifestations and the like. However, soon after 1900 the power potential of crowds began to appear less threatening to the established order (in the sense of general overthrow). Crowds were governable, crowds could be manipulated – this was the new slogan of ruling elites.

An empirical study of Berlin 1900–14 shows the high presence of crowd events in early twentieth-century streets. The events fell into three major categories – 405 street disorders, 74 violent strikes, and 61 political mass manifestations. The ongoing struggle for the city streets is interpreted as conflict between a 'street politics from below' and a restrictive 'street politics from above' carried out by the state power and its police. It was on the political terrain of the street that exaggerated fear of subversion, strict antirevolutionary measures, and socially discriminatory police practice clashed with collective demands for greater social justice and expanded political participation (freedom of assembly, the right to demonstrate, universal suffrage). In a much wider sense, these were demands for respect and self-determination fought out by the proletarian majority in the public forum of the street, the traditional political arena of the common people (Lindenberger, 1995).

For the extremely crisis-ridden interwar period, one can even speak of a culmination of 'street politics,' increasingly transformed (militarized) through the advent of radical political–ideological movements from both the left and the right. In this civil war atmosphere of rabid party political action, with the air filled with bellicose slogans, such as 'self-help' and 'self-defense,' authentic collective crowd action threatened to be instrumentalized and finally suffocated in the battle of totalitarian movements bent on the conquest of state power (for a comparative study of Berlin and Paris 1919–33/39, see Wirsching, 1999).

For some time now the broadening of perspectives has meant the inclusion of non-European regions of Asia, Africa, and Latin America, which have a history of crowds of their own. Important basic forms resemble the European riot patterns: in

the center stood collective claims of peasant producers who rebelled against landlords or large land-holding farmers, urban moneylenders or state organs for reasons of land scarcity, imposed duties, debts, or tax pressure. In the East Asian context, in a series of studies, James C. Scott has shown how peasant behavior was culturally embedded in an all-encompassing subsistence ethic with precise norms regarding access to land, acreage, and a fair apportionment of their own produce. The threats posed to these cultural norms in the context of firmly established clientele relationships might have led to open collective resistance, even if – in consideration of the manifold covert and individual 'weapons of the weak' – this remained more the exception than the rule (Scott, 1976).

In some regions (particularly of China since the eighteenth century, and to some degree of Japan and of India in the nineteenth and early twentieth centuries) the food riot tradition was of considerable historical importance, thus offering comparisons with early-modern Europe (Wong, 1983). At the same time, subsistence conflicts of many Third World regions continue to this day, as confirmed by many contemporary eruptions since the 1970s in North and Central Africa (Egypt, Morocco, Sudan, and Tunisia) and Latin America (Dominican Republic, Venezuela, Brazil, and Argentina). In several cases it was food-riot crowds – whose agitation came in the wake of reduced state food subventions and resulting higher prices – that shook and even toppled ruling governments.

Outlook

The long and hard-fought interpretive battle concerning crowds has been marked by a double disappointment: neither have crowds been shown to be the great negative power, an absolute culture-destroying evil; nor have they been – teleologically speaking – a collective subject to fulfill any historical missions. Crowds have always shown themselves to be multilayered, ambiguous, and variously interpretable phenomena. And naturally, a certain ambivalence remains. For although emancipatory aspects in the sense of subsistence gains, political participation, and self-determination may dominate the phenomenon of crowds, dangerous exclusionary efforts at expulsion or even destruction of religious, ethnic, and other minorities can also be a part of the crowd repertoire. The demythification of the crowd, the gradual opening of political structures to greater popular participation, the modification of collective behavior through historical experience (learning processes that include a growing self-control and adoption of the principle of nonviolence), and other factors may have contributed to crowds having increasingly forfeited their attractiveness as a catch-all for fearful visions or as an instrument for political and ideological agendas imposed from without.

As historical actors in their own right, crowds lay claim to a considerable degree of legitimacy. At the center of this legitimacy stood the collective demands for 'subsistence' (later on: social sharing) and 'liberties' (communal rights, cultural autonomy and, later, political participation) in the context of given governmental and living conditions. Insofar, conflicting crowds were always – more unconsciously than intentionally – indirect collective reformers. Obviously, this seemingly paradoxical role is part of the peculiarities of rebellion and revolution. The political culture of the West – with its human rights norms embodied in the welfare state and democratic institutions since the end of the nineteenth century – would have never attained to the stature it occupies today had it not been for persistent collective intervention from below. Crowds have helped to draw up the agenda for social and political human rights, and they continue to do so.

Where comprehensive systems of social sharing and political participation have been historically established and long in place, crowds tend toward a shift in their forms and motives. From a purely quantitative standpoint, protesting crowds in recent times have been anything but on the decline. To the contrary, they have been on the upswing, becoming a conventional part of political culture. Although violence has receded, it has not fully disappeared. Rating high are questions other than elementary ones of subsistence and freedom. Demands for social and political egalitarianism have for some time taken a backseat to new values and fresh demands based on 'new social movements.' Those groups affiliated with crowd events are no longer predominantly or exclusively from the lower classes, but are a great mix of people with considerable representation from the public sector, education, science, and culture. Fitting in well with these trends is also the upsurge of class nonspecific leisure crowds in the context of new event cultures.

As an elementary form of the public sphere (*Versammlungsöffentlichkeit*), crowds will endure. Certainly modern mass media have continued to occupy strongly the public arena, becoming themselves more and more an embodiment of the entire public. But talk shows have hardly rendered crowds superfluous. Albeit today's media presence largely determines the public perception of crowd events, thereby heavily influencing their effectiveness. In their endless variety, crowds represent the unmediated, face-to-face public. Such gatherings of people for purposes of social and communicative self-awareness are apparently a deep-seated human need that – despite the relative dwindling of traditional conflicting crowds – will not soon disappear.

Abstract

The Cuban Revolution imbued confidence to reformists and revolutionaries in 1959. Castro's challenge to American hegemony and promises of an independent socialist society came to naught as Cuba became a satellite of the Union of Soviet Socialist Republics (USSR). The breakdown of the Soviet bloc and USSR's collapse ended the subsidies that sustained the system despite the embargo enforced by the United States of America. Cuba's tourist industry, export of Cuban labor, the Internet, and the regime's diminishing coercive power have fostered internal challenges. In 2008, Fidel Castro turned power over to Raúl Castro, his octogenarian younger brother, who started limited economic reforms in an attempt to ensure the regime's survival under the Party's dictatorship. The 2011 economic reforms threaten the safety-net that characterized the revolution.

Introduction

The Cuban Revolution infused confidence throughout the world in 1959. Fidel Castro's challenge to American hegemony and promises of an independent socialist, egalitarian society came to naught by the late 1960s as Cuba became a Caribbean satellite of the Union of Soviet Socialist Republics (USSR). The revolution's draconian political and economic policies soon prompted a massive entrepreneurial and professional middle class exodus despite the government's ban on travel abroad. The dearth of qualified labor had grave consequences for the island's economy. By 1980s, the breakdown of the Soviet bloc and the USSR's collapse ended the magnanimous subsidies through which the regime survived. Failed economic programs and military adventurism caused the citizenry's abject poverty and dependency on remittances sent by relatives in the diaspora. The exploitation of Cuba's natural tourist attractions, the exportation of Cuban labor to obtain foreign exchange, and the regime's diminishing coercive power have promoted internal challenges, as the population comes in contact with the free world. In 2008, Fidel Castro turned power over to Raúl Castro, his octogenarian younger brother, who started economic reforms in an attempt to ensure the regime's survival under the Party's dictatorship.

From Spanish Colony to Republic

From 1895 to 1897 the Cuban war for independence from Spain had become a protracted struggle. US intervention and occupation ended the war in 1898 and although Cubans constituted the land forces facilitating the swift American victory, they were ignored during the Treaty of Paris negotiations. The US aided the war-torn country, improving health conditions and education. American investments and return of Spanish capital contributed to economic recovery. US occupation ended in 1902 after Cuban delegates to the 1901 Constitutional Assembly capitulated to American pressure and appended the Platt Amendment to the Cuban Constitution. The amendment, imposed by the US as a requisite for ending the occupation, gave Americans the power to intervene militarily and restricted Cuba's international relations.

Traditional and pseudo-Marxist historiography reduces US–Cuban relations to events during and after 1898. This perspective marks 1898 as the date when Cuba was no longer a Spanish colony and became a US protectorate. The truth is more complex. Since the mid-nineteenth century, despite being a Spanish colony, the island's economy depended on US trade. Cuba was the world's foremost producer of sugar and the US imported 90% of Cuba's production. The US was a refuge for Cubans aspiring independence and, under José Martí's leadership, Cuba's first political party was created in the US. Martí, although not anti-American, opposed US intervention. Economic ties continued to play a role in US–Cuban relations during the Republican Era.

The Early Republic

Liberalism, electoral fraud, administrative graft, and civil unrest characterized the early republic. Creole elites were nearly destroyed as Spain did not compensate Cubans for property losses. The postindependence concentration of US and Spanish capital in the sugar industry, together with the Spaniards' control of banking and commerce, made access to public office a vehicle for upward mobility for Cubans. Armed struggle was often a means to ensure circulation of elites in government. After intervening militarily in several occasions, the US occupied the island for a second time from 1906 to 1909.

By 1902, Cuba had become the world's second largest sugar producer despite extensive war damages to its agriculture. Although plantations were ravaged by fire, the sugar industrial sector sustained limited damages. Only seven of the 50 largest mills were destroyed and four experienced minor losses (Moreno Fraginals, 2001: p. 485). A Cuban-born entrepreneurial class emerged as sugar production and prices rose during and after the First World War. In the early 1920s, the Cuban banking crash and the collapse of sugar prices plunged

[†] Deceased.

the nation into chaos. By 1923, widespread discontent led to demands for curtailment to foreigners' concessions, abrogation of the Platt Amendment, and an end to sugar dependency.

The 1933 Revolution

Gen. Gerardo Machado's dictatorship (1925–33), US interference, and plummeting sugar exports led to the 1933 Revolution and a provisional government installation. On 14 September declaring Cuba would only honor "spontaneously" signed treaties, Ramon Grau's administration unilaterally repealed the Platt Amendment (Carrillo, 1985: p. 267). Cuba's emissary to the VII International Conference of American States on the Rights and Duties of States ratified Cuba's Platt Amendment's repeal on December 1933 in Montevideo. Opposition to the social, economic, and political reforms enacted by Grau's administration prompted the US Ambassador's request for American military intervention. Instead, the US withheld diplomatic recognition of Grau's government. On January 1934, Sgt. Fulgencio Batista, promoted as army staff chief, deposed Grau with US Embassy support. The 1933 Revolution challenged US hegemony, introduced socioeconomic and political structural changes and established, for the first time in history, a free Cuba. On 29 May 1934, a new US–Cuba treaty was signed, ratifying Cuba's repeal of the Platt Amendment, which US had tacitly agreed to rescind when US Secretary of State Hull signed the Conference's Final Act in Montevideo on December 1933 (Portell-Vila, 1986: p. 431).

The Republic's Failure

Batista ruled by proxy until elected president in 1940. In 1944, the Partido Revolucionario Cubano (Auténtico) came to power when Dr Ramón Grau was elected president. The reformist policies enacted during Grau's previous short presidential term had been incorporated into the 1940 Constitution. Unfortunately Grau's second term and subsequent Auténtico government of Carlos Prío (1948–52), although infused by the 1933 Revolution's agenda, were characterized by public sector graft, corruption, and political gangsterism.

In 1947, Eduardo Chibás, founded the Partido del Pueblo Cubano (Ortodoxo), which embodied the hopes of a generation for whom the 1933 Revolution's promises remained unfulfilled. Honesty in public office was the core of Chibás's movement and his 1951 suicide created a leadership vacuum. On 10 May 1952, 2 months before elections, a coup led by the ubiquitous Fulgencio Batista, ended the constitutional republican experience. On 26 July 1953 in Santiago de Cuba, Fidel Castro led the unsuccessful attack on the Moncada barracks, which drew publicity to him and his Twenty-sixth of July Movement (M-26-7). After Batista refused to concede the demands for free elections by a coalition of leaders seeking a nonviolent solution to the crisis, violence escalated. The Federación Estudiantil Universitaria (FEU) called for a strike. In 1956, Castro and José A. Echeverría, FEU president and leader of the Directorio Revolucionario Estudiantil (DRE), joined forces to depose Batista. By December, Castro had established guerrilla operations in the mountains of Sierra Maestra. On March of 1957, the Auténticos and the DRE, without collaboration from M-26-7, stormed the presidential palace and in a separate incident during the failed assault Echeverría was killed. As government repression mounted, professionals and entrepreneurs joined the fight and other guerrilla fronts emerged. Between 1956 and 1957 conspiracies were discovered in the armed forces, and the urban underground initiated a terrorist campaign. In 1958, the US imposed an arms embargo on Batista's government. A military offensive against the rebels failed and the rebels mounted a counteroffensive. At dawn, on 1 January 1959, Batista fled the country leaving behind a provisional junta. His escape also left an astonished and enraged Castro as he found himself in Oriente province, over a 1000 km away from the center of power while the regime collapsed.

Communist Revolution

After a short period of confusion as anti-Batista groups vied for power and Batista's army surrendered to Castro's rebel forces, the unanticipated communist revolution began. The Cuban Communist Party, Partido Socialista Popular (PSP), barely participated in the struggle against Batista until 1958 and Castro emphatically denied any communist inclinations. Castro's social and economic programs were based on the implementation of the 1940 Constitution's provisions.

On the revolution's eve, Cuba was a developing nation ranked among the top five Latin American countries. The movement to depose Batista had a heterogeneous class base, although the urban underground was primarily comprised by members of Cuba's growing middle class. The movement was neither antibourgeois, nor anti-American. Castro's M-26-7, as well as other anti-Batista groups, focused on issues concerning the middle classes: political freedom, constitutionality, and fiscal integrity.

Origins of the Revolution and Leadership Legitimization

The complexity of Cuban society and of revolutions in general, becomes evident as one surveys the literature on the causes of the Cuban revolution. Draper (1962) claims it was a middle-class phenomenon. Suárez (1967), among others, argues it was the product of Castro's charismatic leadership and political maneuvering. To Aguilar (1972) it was the frustrated 1933 revolution and the absence of reforms. Domínguez (1978) emphasizes that the fragmentation and individual strength of Cuba's civil society in prerevolutionary politics allowed the revolutionary process to crystallize after 1959. Farber (2006) argues the stage for a revolution was laid in the republican period and Castro, once in power, counterbalanced US belligerence with Soviet support.

Cuba's official historiography proclaims a single revolutionary movement beginning in 1868, combining two separate attempts at independence despite their diverse regional and class composition, and ends with Castro's 1959 triumph. Thus both anticolonial nationalist wars, seeking the establishment of an independent democratic republic are portrayed as a single socialist revolution. In 1968, the leadership reinstated the 10th of October, a patriotic date marking the beginning of the Ten Years War, to proclaim themselves the true liberators of Cuba 'after 100 years of struggle." Through symbolic manipulations

Cuba became synonymous with revolution and the revolution synonymous with Fidel Castro (Pérez-Stable, 1999).

Revolutionary Dynamics

The leadership implemented typical totalitarian strategies. Guevara expounded on the need to create a new economic base and a 'new man.' Policies reminiscent of fascist tactics sought to uproot prerevolutionary organizational and interpersonal patterns. The institutions of work and education, radically transformed, became the focus of Cuban life. The government monopolized all means of communication. Slogans with the names of key figures were incessantly repeated through all forms of media (Medin, 1990). Attempts were made to destroy the traditional family structure and institutionalized religion was crippled (Pedraza, 1998). Mass organizations were responsible for transmitting the new ideology, mobilizing the population, and maintaining constant vigilance. The trials, executions, long jail sentences and feelings of constant surveillance unleashed the 'terror' stage. Political parties, elections, freedom of the press, labor's right to strike were eliminated, and universities and unions purged. The 1940 Constitution was proclaimed outdated, and the US became Cuba's enemy. All criticism was counterrevolutionary and political opponents were imprisoned or executed. A pattern of negative integration (Groh, 1973) developed as Cubans that opposed the system and were unable or unwilling to leave, survived by pretending acquiescence.

Economic Crisis and Revolutionary Euphoria (1959–70)

Between 1959 and 1961, Cuba was transformed. Foreign and domestic properties were expropriated and Cuba's foreign relations changed rapidly. Soviet military advisers and weapons started arriving by September of 1960. In October, the US imposed a trade embargo and by January 1961 Cuban–US diplomatic relations were severed. The Bay of Pigs invasion's failure and concomitant detention of approximately 100 000 opponents crushed the underground cementing the revolution. The massive urban middle class exodus intensified with the departure of those who had fought against previous oppressive regimes, leading to the creation of a Cuban diaspora of more than two million exiles. On the invasion's eve, Castro proclaimed, for the first time, the revolution's socialist nature. One month later, Cuba–USSR relations were reestablished. The Soviet connection may have been initiated in the late 1950s by Raúl, Fidel Castro's younger brother through contacts with the international communists while at Sierra Maestra (Bonachea and San Martin, 1974). On 2 December 1961 Castro declared himself a Marxist-Leninist.

A crisis between the superpowers ensued when a US reconnaissance plane discovered Soviet missiles and launching sites in Cuba. The Missile Crisis's outcome altered Cuba's foreign policy. Castro felt betrayed, although all viable external threats disappeared when the US agreed not to invade Cuba in exchange for the missiles' removal, as the compromise was reached without consulting him. Castro reacted by imprisoning the island's pro-Soviet communists and seeking new allies throughout Latin America. The USSR retaliated by decreasing petroleum deliveries to Cuba compounding the catastrophic failure of the revolutionary economic policies. In 1968, to stay in power, Castro affirmed Soviet hegemony by supporting the Soviet invasion of Czechoslovakia. Cuba's ill-conceived strategies of attempting to industrialize, while neglecting sugar production and exchanging the US as trading partner (140 km away) for the USSR (over 4500 km away), resulted in mounting indebtedness. Although the sugar industry had been devastated since 1964, a ten-million ton sugar harvest was programmed to solve the crisis.

As revolutionary euphoria subsided, all those demonstrating disaffection were drafted into Units to Aid Production (UMAP). From 1965 to 1967, priests, seminarians, homosexuals, juvenile delinquents and those deviating from socialist orthodoxy were placed in UMAP concentration camps. In 1968, the 'Revolutionary Offensive' eliminated all vestiges of economic capitalism by closing remaining small businesses. Workforce absenteeism, low productivity, and poor product quality were the population's reaction to moral incentives.

Institutionalization and Foreign Military Adventurism

Material incentives returned by 1970, when Soviet type economic models were introduced. In 1974, Brezhnev's visit strengthened Cuba–Soviet relations. One year later, Cuban African campaigns began with Soviet support. By the 1980s, Soviet subsidies reached $3 billion a year. The USSR supplied 90% of the island's oil needs and an inordinate proportion of basic foodstuffs. Although this aid improved living standards, over 120 000 Cubans abandoned the island during the 1980 Mariel Boatlift. In 1986 Castro launched the 'Rectification of Errors Campaign' eliminating material incentives and market reforms. Mass mobilization and volunteer work were reintroduced. Castro's policies, in conjunction with the Soviet bloc breakdown and subsequent USSR collapse, propelled a severe economic crisis. The US embargo became a weapon for the first time since its inception after Cuba ceased receiving Soviet subsidies. In 1989, General Arnaldo Ochoa and Colonel Antonio de la Guardia were accused of drug dealing and breaching national security. The dismantling and purging of several government agencies followed their trial and execution, as growing dissension could no longer be ignored.

Last Decade of the Twentieth Century

In 1990 the 'Special Period in Peacetime' was declared and policies were adopted to develop an autarkical state. To alleviate food and energy shortages, thousands of urbanites were moved to the countryside to work in food production. Austerity and mass mobilization were expected to solve the country's crisis, until foreign investments, tourism, and an incipient biotech industry could generate the necessary hard currency.

Castro declared his unswerving commitment to socialism in 1991; vowing that neither political nor further economic reforms would be implemented. By 1993 the mounting crisis made economic reforms inevitable. Farmers' markets, duty-free zones and 'dollarization' were instituted. Access to dollars, mainly through exile remittances, tourism, and illicit activities, such as prostitution and black-market participation, provided

economic respite to a segment of the population while contributing to the public's growing awareness of emerging socioeconomic disparities. Since the late 1960s, upper government cadres had been the only groups known to enjoy goods prohibitive to the rest of the population; access to hard currency now allowed other segments to acquire those goods.

As Castro suspected, the government's incapacity to continue its role as sole provider of the nation's needs eroded the state's coercive power. Religious participation increased, critics became more vocal, human rights groups multiplied, and short-lived rebellions erupted. In 1994, another mass exodus occurred. Over 30 000 people, in unique makeshift inner tube rafts, abandoned Cuba.

The embargo was reinforced by the 1996 Helms-Burton Act after Cuban MiGs downed two light planes belonging to 'Brothers to the Rescue,' an exile organization flying over the Strait of Florida searching for rafters. Regime criticism increased as International Labor Organization (ILO), Amnesty International, and the United Nations repeatedly condemned Cuba's human rights violations. Pressures for the US to lift the embargo also proliferated. In 1998 the Christian Liberation Movement in Cuba launched the Varela Project under the leadership of Oswaldo Payá, who opposed both the US embargo and Cuba's human rights violations. The Varela Project, aimed at amending the Cuban constitution, gathered the constitutionally required number of signatures for a referendum. To date, the government has refused to bring the proposal up for discussion at the National Assembly. The twentieth century came to a close with the continued isolation of Cuba, despite Pope John Paul II's bid for Cuba to open to the world and for the US to end the embargo during his 1998 visit.

The Cuban Revolution in the Twenty-First Century

The perpendicular decline of Cuba's floundering economy since the 1980s continued into the next century despite sporadic hiatuses of recovery. The crises provoked by the 9/11 terrorist attacks and the 2008 global depression further exacerbated the island's inherent economic woes.

Old and New Problems

When Castro announced the 'Special Period in Peacetime' in 1990 no one anticipated that the catastrophic conditions forcing such measures would return in the twenty-first century (Gonzalez-Corzo, 2010). Assuming control, Raúl Castro acknowledged both the failure of the socialist economic experiment and that saving socialism would require market-oriented capitalist reforms. A total of 1.8 million public sector jobs were earmarked for elimination by 2014 and more occupations, mostly service categories (*cuentapropistas*) legalized in 2010, were added to the 178 list of self-employments (Scarpaci, 1995). Decriminalized occupations authorized by these guidelines had long been part of the underground economy and the government now hopes to benefit through imposed heavy taxation on earnings. Strict regulations on *paladares* (small restaurants) licensed in 1993 were also relaxed (Henken, 2011).

Foreign Exchange

Although sugar was the foundation of the Cuban economy since the 1800s and the island the "world's sugar bowl," revolutionary policies and technological obsolescence led to the importation of sugar to satisfy internal demand by 2011. Since the late 1970s, numerous efforts had been made to develop other hard currency sources beyond the traditional exports of sugar, rum, tobacco, and minerals. A biotech industry, tourism, oil resales, joint ventures, and the commodification of labor are among those economic strategies. With the exception of biotechnology, the rest achieved some success.

Tourism

For 15 years, tourism, which had been an important revenue source since the 1920s, was eliminated through revolutionary policies and the US–Cuba conflict. In the 1970s, sugar no longer satisfied hard currency needs and the Instituto Nacional de Turismo (INTUR) was established. Tourism was once more a national industry (Aagesen and Paluch, 2000).

Legalization of foreign ventures in the 1980s revitalized tourism. The four S's of Cuban tourism: sea, sun, sand and sex were again internationally recognized. Tourism and prostitution became linked as they were prior to 1959, but tourism presented new dilemmas for the socialist government as capitalism gained a stronghold within the island. The initial solution was to develop tourist enclaves only for foreigners as Cubans were denied access to these amenities (Pérez-Lopez, 1994). The Cuban "apartheid" became a domestic political issue. Economic inequalities also surfaced between those permitted to work in tourist facilities and those barred. After a meteoric rise, the tourist industry stagnated mainly due to the 9/11 terrorist attacks, the 2008 global recession, and growing tourist dissatisfaction with services provided.

Oil Resales and Joint Ventures

As Yanes (2005) indicated, baptizing the 2005 yearly slogan as the "Year of the Bolivarian Alternative for the Americas" served to acknowledge Venezuela's crucial role in the survival of Castro's regime. Venezuelan subsidized oil solved the domestic energy crisis while providing Cuba access to hard currency through its resale; estimated to represent US$1000 million dollars annually. Cuba's indebtedness to Venezuela is evocative of the Soviet–Cuba alliance. The Institute for Cuban and Cuban–American Studies reports that by 2001, after European Union (EU) members' credits extended to Cuba were withheld due to repeated payment defaults, and Venezuela displaced Spain as Cuba's top trading partner (Cuba Transition Project, Institute for Cuban and Cuban–American Studies, 2002). In 2009, Cuba–Venezuela trade reached $10 400 million (Romero, 2011). Oil refineries are being built with Venezuelan and Chinese funds in both coasts and the possibility of finding significant oil deposits in Cuba's north coast is being explored.

Commodification of Cuban Labor

During Castro's 1962 medical faculty inaugural address, Cuba's internationalist proletarian policy was announced (Maury del

Toro, 2010). Revolutionary internationalist solidarity has brought the regime such a political and economic bonanza that medical schools are mushrooming in Cuba. By 2008 revenues from export of labor had tripled tourism receipts. Cuban proletarian exports include physicians, dentists, nurses, medical technicians, teachers, engineers, architects, and other technical personnel. Medical brigades have been sent to Latin America, Africa, Asia, and the Middle East. Sending emergency brigades mostly financed by third party payments to Cuba or by the country receiving the services during disasters, opens the door for government-to-government accords. Developed countries and international organizations provide the lion's share of funds financing Cuban brigades, while the recipient countries mostly provide personnel housing and board. Cuba's missions have been funded by Brazil, France, Germany, Japan, Norway, South Africa, Zimbabwe, and Venezuela. The Pan American Health Organization (PAHO), United Nations Children's Fund (UNICEF) and World Health Organization (WHO) are among major international institutions bankrolling Cuba's health brigades (Werlau, 2011). Cuba's solidarity is humanitarian, but it is not free.

These agreements violate International Labor Organization (ILO) statutes, and the International Declaration of Human Rights (De Cuba, 2011). Cuban personnel do not participate in the accords. Neither their salaries nor working conditions are negotiated by them. Their pay rate is the Cuban $200 a month salary, although funding agencies pay the Cuban government over 10 times the amount. They are forbidden to move outside the deployment area; required to maintain surveillance on all mission members; report host country conditions, and are under Cuban security forces' strict control (Werlau, 2010)

Domestic Politics

After five decades in power, the old and fatigued revolutionaries continue to reaffirm that despite growing demands for freedom there will be no political reforms. Economic reforms are means to build socialism under Party control. Marino Murillo, at 51 one of the youngest recently appointed Politburo members, stated that while Cuba is liberalizing its economy and welcomes foreign investor partners, no concomitant changes in the political sphere will occur. Murillo's declarations were the government's response to Pope Benedict XVI's calls for Cuba to evolve into an open society during his March 2112 visit (CBS, www.cbsnews.com/2102-202_162-57405199.html)

New Challenges

The greatest challenges faced by Cuban authorities are internal corruption and claims from sectors for which the promises of the revolution were not fulfilled. Afro–Cubans, women, and youth are making their demands known through the new media at their disposal. Despite government's efforts to maintain Cubans under the revolutionary rhetoric's spell, a new revolution beyond its control and its borders infiltrated the island. The Internet and cellphones are providing the population with uncensored information and means to make their frustrations known.

Corruption

All governments deal with corruption and centrally planned economies concentrating power in the hands of government bureaucrats are plagued by it. Cuba is no exception, despite Castro's commitment to end corruption. By 1981, 92% of the workforce was employed by the state, making the majority of workers public bureaucrats. During a 20-year period (1968–88), all economic activity came under the state's control, with the exception of agriculture and transportation in which the government exercised 97 and 99% control respectively (Diaz-Briquets and Perez-Lopez, 2006). Chronic consumer goods scarcity experienced since the 1960s turned diversion of state resources, graft, theft, bribing and participation in the black market a common practice.

The danger corruption poses to a revolutionary discourse focused on the creation of an egalitarian society is obvious to regime's supporters. An island academic published an article questioning whether corruption could be the real counterrevolution, as it is entrenched within government structures (Morales-Dominguez, 2010). Citizens' awareness of privileges enjoyed by groups at the top echelons has been documented through interviews of those leaving the island since the 1970s; and, by the 1990s, dollarization and tourism expanded the number of groups perceived as privileged beyond the confines of the revolutionary elite (Clark, 1999). Public accusations of malfeasance and anticorruption campaigns have been made by both Castro brothers since the 1960s. Raúl Castro initiated a crackdown on corruption after succeeding his brother by purging government officials and foreign companies' executives (Acosta, 9 November 2011).

Race Relations

Cuba, as common to other societies in which African slavery was practiced, has a legacy of racial prejudice and discrimination. Cuba's difference is that no other society claims eliminating racism by decree. Continued discrimination charges, including police racial profiling, are widespread (Miami Herald Staff, www.miamiherald.com/multimedia/news/afrolatin/part4). Blacks also claim they are discriminated from hard currency economic sectors, such as tourism.

Despite socioeconomic gains, the proportion of blacks at the top of the power structures is negligible and the advances achieved through policies instituted to improve the poor's living standards, where the majority of the black population concentrated, have been eroding since 1980s economic crisis of the (Morales-Dominguez, 2007). Exile remittances are estimated at $1.5 billion a year, but less than 15% among Cuban exiles in the U.S are black or mestizo (Ennis et al., 2010 Census Brief: p. 15).

Estimates of Cuba's racial composition vary according to the criteria applied to determine racial boundaries. If the North American dichotomy is used, the majority of Cubans would be considered black. Applying the Iberian classification based on phenotype (Hoetink, 1967), which is normally used by Cubans, the population is segmented into three layers in which the white and mestizo groups comprise a statistical majority. Thus, the 2002 Cuban Census reported that the population was: 65.1% white; 24.8% mestizo; and only 10.1% black. The

only segment that, according to Cuban census figures, has unequivocally continued to increase is the intermediate mixed category. Since 1953 the white population decreased by 8% and the black segment dropped 2%. The political realities of a society in which race continues to matter are palpable by the government's attempts at inclusion of more members of the mestizo and black population in the power structure. Raúl Castro promoted some blacks, mostly women, to Council of Minister posts (Partido Comunista de Cuba, www.pcc.cu/eo_secretariado.php). The Council now counts with 31 white, 3 black; and 2 mestizo members. The 14-member Politburo maintained its quota of 2 black males, and added a new female mestizo member. A similar maneuver was implemented at the Party's Secretariat, in which out of the 7 officials that compose it, the sole black male – also a member of the Politburo – was joined by a younger mestizo female (Partido Comunista de Cuba, www.pcc.cu/eo_buro_politico.php). Black dissatisfaction with the state of affairs is evidenced by increasing numbers of blacks among dissidents and the creation of black civil rights groups. Some of the best known figures within the growing dissident movement are black, such as physicians Oscar Elías Biscet and Darcy Ferrer, journalists Guillermo Farinas and the late Orlando Zapata Tamayo who died while on a hunger strike in prison.

Women: The Birth Dearth and Political Protest

A patriarchal ideology always framed women's position in Cuba and the 1970s militarism further eroded the status of women. The initial objectives of the Federation of Cuban Women (FMC), founded under the direction of Raul Castro's late wife, Vilma Espín (1930–2007), were to develop women's socialist consciousness and to organize them in defense of the revolution. Cuban women would be repositories of Cuban-Marxist-Leninist ideology and reproducers of human capital for revolutionary purposes. FMC's membership grew throughout the 1970s, and women were encouraged to do volunteer work and join the workforce. The renewed emphasis on developing an economy based on sugar production forced women to join the urban workforce to fill vacancies created by the transfer of men to agriculture during the Ten-Million-Ton-Sugar Harvest.

The FMC defense of women's rights partly eliminated discriminatory policies proscribing women from hundreds of jobs. Women's government employment rose in tandem with educational levels. Still, patriarchal values continued to undermine women's equality as men refused to share domestic obligations. Women's burden increased exponentially as they had to allocate time to family, work, education, and revolutionary responsibilities. In the late 1980s female academicians addressed Cuban gender disparities by initiating research ranging from domestic violence to women's double-shift (Acosta, 12 October 2011). Interest in gender studies coincided with the alarm over a sustained drop in birth rates.

Cuba's demographic transition started early in the twentieth century due to economic downturns of the 1920s and 1930s and growing women labor market participation. The crude birth rate in 1958 was 28.1 per 1000; well below rates for other developing countries. After a postrevolutionary baby-boom (1959–66), birth rates rapidly declined. Birth rates have been below replacement level since 1978. Several explanations have been advanced for this decline. Alfonso de Armas (2009) enumerates public health care availability, sex health education, increasing gender egalitarianism, and access to legal abortions with few restrictions; Andaya (2007) maintains it is linked to the convergence of modernization and underdevelopment; and Díaz-Briquets and Pérez (1982) believe that unmet rising expectations is the key determinant.

Cuban women claim they would have more children if they could provide for them (Grogg, 2009). They cite lack of resources, low salaries that hardly cover basic needs, chronic food shortages that consume most of their income and day searching from government stores to black market providers; and absence of adequate housing and daycare (Sánchez, Y., 2011). Most unwanted pregnancies end with abortion. Public Health Ministry (MINSAP) 2008 data indicate that there were 23.0 abortions per 1000 women aged between 12 and 49 years old (Gran Alvarez, 2005). Under the euphemism of "menstrual regulation service," vacuum-aspiration abortion is available up to 7 weeks without confirmation of pregnancy. This method, implemented in 1968, is the prevalent procedure for ending pregnancies. The fertility decline coupled with an aging population and the migration of younger cohorts threatens to invert the island's age pyramid (Coyula March 2010).

In 2003, after a group of 75 dissidents including journalists, librarians, and human right activist were tried and condemned to prison terms ranging from 6 to 28 years, their female relatives started peacefully marching to demand their release. The group came to be known as the Ladies in White. Their founder, the late Laura Pollán, was awarded the 2005 Sakharov Prize, which the Cuban government did not allow her to receive by denying her permission to travel abroad. Originating in Havana the group spread to other cities. The men were dispersed throughout Cuba's prison system; isolating them from their local communities. This strategy, designed to also inconvenience relatives by forcing travel in the midst of Cuba's transportation and economic crisis, had the unintended consequence of contributing to the movement's proliferation as the women networked with other convict's female relatives. Despite government's repression and Laura Pollán's death in October of 2011, the Ladies in White continue defending prisoner's rights.

Human Rights

The number of political prisoners in Cuba remains undetermined. The Cuban Criminal Code stipulates that any potential violation of norms is a criminal offense identified under the law of dangerousness, which can lead to detention, trial, and conviction (Amnesty International 2011 Report). Citizens distributing leaflets with the Universal Declaration of Human Rights, gathering signatures for a referendum, or attempting to organize unions have been detained and convicted under this law. Lack of participation in official events, moving outside of one's registered domicile and even unemployment due to disability have been cited as crimes under this code leading in some cases to "official warnings" and in others to years of imprisonment (World Report: 2012. Cuba, Human Rights Watch). Cuba prohibits all political dissent. Cubans that challenge the system face charges and

risk enduring verbal attacks, beatings, recurrent short-term detentions, and years behind bars. The release of political prisoners is usually contingent on forced exile. Although Cuba refuses access to prisons by international human rights organizations, information released by domestic human rights defenders, by ex-prisoners or by their relatives, indicates that Cuban prisons are unsanitary and overcrowded. Prisoners are denied medical care, subjected to beatings, prolonged solitary confinement, and forced to submit to ideological rehabilitation.

In violation of the Universal Declaration of Human Rights, travel within the island without official authorization is restricted by Decree 217 (Human Rights Watch, 1999). Cuban citizens are also forbidden to leave or return to the island without official permission.

The World Wide Web, Cellphones, and Bloggers

Cubans were semiisolated from the world for decades. The revolution in global communications coincided with the socialist camp demise and Cuban authorities' needs for hard currency. The tourist industry demanded a communication infrastructure for hotels and areas linked to the tourist economy; and, as spaces emerged beyond the government's absolute control, the population gradually initiated national and international contacts. Bloggers committed to free expression have ingenuously devised channels to publish abroad.

As the power to coerce the population through its absolute control of the economy diminishes, the state now relies on tactics common to authoritarian regimes, such as public acts of repudiation, intermittent short-term arbitrary arrests and grueling interrogating sessions. Presently, the victim's friends or relatives can report these violations to human right groups abroad mostly through cellphones. Public verbal and physical attacks of dissenters by mobs of government supporters, incited and organized by security police posing as civilians, have been photographed or videotaped by witnesses and transmitted via cellphones to the rest of the world; and, although bloggers are harassed, detained, and subjected to government slander, the government has been unable to silence them. Cuba's best known blogger, Yoani Sánchez was awarded the 2009 Maria Moors Cabot Prize by Columbia University's Graduate School of Journalism and Guillermo Fariñas, independent journalist and member of the 75 dissidents tried, convicted, and imprisoned during the 2003 Black Spring, was conferred the 2010 Sakharov Prize for Freedom of Thought. Both were denied permission to travel and were unable to receive their awards. In a crackdown prior to Pope Benedict XVI's visit, Cuban police detained and intimidated dissidents. While the pope visited Cuba, in an effort to block any uncensored coverage of the events, all calls to dissidents' cellphones were diverted to the Interior Ministry (Tamayo, *Miami–Herald* 2012). The Ladies in White contacted foreign media sources before the pope's arrival to report the ongoing harassment campaign; and, during the papal mass in Santiago de Cuba on 26 March, Andres Carrión was caught on tape as he was dragged by the secret service and beaten by a Cuban Red Cross employee while shouting antigovernment slogans (Leon, Miami-Herald 2012).

US–Cuban Relations

From the 1963 Missile Crisis to the 1980 collapse of the Berlin Wall, Cuba's safety was guaranteed by a standoff between the superpowers. If the Soviets moved on Berlin, the Americans would invade Cuba (Freedman, 2000). At the end of the Cold War, Cuba found itself an orphan in a changing world. Cuba was no longer a prize to be had, nor a threat to Latin American stability. The US embargo began to exact a toll and Washington, despite its uncompromising rhetoric saw no reason to deny American businesses the benefits from a market 140 km from its shores. The Trade Sanctions Reform and Export Enhancement Act (TSRA), signed into law in 2000, provided the legal framework for renewing trade with Cuba. The United States now ranks as Cuba's fifth trading partner, while Cuba ranks among the top 10 importers of American agricultural and food products. The embargo, which only remains as a symbolic sanction, has provided Cuba the excuse for its economic failures during five decades.

In 2008 two major changes in leadership occurred as Castro's resigned in favor of his younger brother Raúl and Barack Obama's election brought the Democratic Party back to the White House. Neither of these changes altered US–Cuban foreign relations significantly. Although the Obama administration seemed to be willing to broaden the dialogue with Havana – the stringent restrictions imposed on travel to Cuba under Bush's administration were eliminated and the dollar amount of remittances sent from the US to the island was increased – the 2009 Cuban government's detention of Alan Gross, an American that regularly traveled to Cuba, hindered further rapprochement (Chavez and Tamayo, 2011). Gross' detention coincided with the 2009 US Supreme Court decision not to hear the appeal of members of a Cuban spy-network operating in the US (Chacón, *Boston Globe*, 2001) Gross, identified by Cuban authorities as an American agent, was subsequently tried, and convicted to 15 years for crimes against the state. US–Cuban relations have reached an impasse as both governments continue to pressure for the release of their respective agents as a prior condition for negotiations.

Conclusion

Cuba entered the second decade of the twenty-first century under the control of a military gerontocracy headed by the Castro brothers and what remains of their loyal clique of 1960s revolutionaries. The revolution's greatest success continues to be this group's ability to stay in power. The regime's coercive power, although diminished, is still able to crush dissent through intimidation or outright violence. The Cuban chronic economic plight and reliance on external support reminds one of Blanche DuBois line "Whoever you are, I have always depended in the kindness of strangers" in *A Streetcar Named Desire* by Tennessee Williams. The system survives through the aid or charity of other nations; with other people's money, be it Soviet, Venezuelan, Canadian, Spanish or the hard currency earned through the exploitation of Cuban medical and technical personnel sent as humanitarian missions; and last, but not least, the remittances sent by Cubans residing in the

constantly growing diaspora. The recent reforms include substantial cuts in health care, education, employment and food subsidies. These austere policies undermine the meager safety net the revolution provided. If a private sector is to satisfy the basic physical and nutritional needs of the citizenry, the reforms would have to go beyond the paltry measures adopted to liberalize agricultural production and real estate sales.

Cultural Capital and Education

Susan A Dumais, Lehman College, City University of New York, Bronx, NY, USA

Abstract

This article provides the definition(s) of cultural capital and its theoretical context, with a particular focus on the relationship between cultural capital, schooling, and educational outcomes. An overview of Bourdieu's theory of social and cultural reproduction is given, focusing on the role of cultural capital. Empirical research on various operationalizations of cultural capital, both quantitative and qualitative, and various educational outcomes, are reviewed; research from multiple nations is represented. Past and current controversies regarding the cultural capital concept in educational research are discussed, as they are important directions for future research.

Introduction

Cultural capital has been a widely used concept in sociological and educational research in the last several decades. Originated by Pierre Bourdieu to describe educational inequality in France, the concept has now been explored around the world and has taken on a number of different operationalizations in qualitative and quantitative research, from all levels of schooling ranging from elementary school to postsecondary education. Findings regarding the effects of cultural capital are mixed, with some supporting the idea that cultural capital increases educational rewards, others finding a negative or no effect, and others finding different effects based on the characteristics of the group being studied (with variations by gender, race, and social class). Although a popular concept, some critics debate its usefulness or the approaches that researchers use to study it. Nevertheless, the concept is a fruitful one and new directions in using it are developing within sociology and educational research.

Definitions of Cultural Capital

Bourdieu's Definitions

Pierre Bourdieu developed the concept of cultural capital in the late 1960s when studying the French educational system and noticing that middle-class students tended to persist through school, while working-class students had higher drop out rates. Bourdieu argued that although education was supposed to serve as a vehicle for social mobility where students could work to their natural aptitudes, the educational system actually reproduced the existing social class structure; one important mechanism through which this reproduction occurred was cultural capital. In "Cultural Reproduction and Social Reproduction," Bourdieu described cultural capital as "linguistic and cultural competence and that relationship of familiarity with culture which can only be produced by family upbringing when it transmits the dominant culture" (1973: p. 80). The cultural capital recognized and rewarded by teachers and the school system was the kind possessed by the middle and upper classes.

Bourdieu distinguished between three forms of cultural capital: embodied, objectified, and institutionalized. Embodied cultural capital referred to one's tastes, ways of speaking and carrying oneself, and general knowledge of the culture valued by the dominant classes. Objectified cultural capital referred to objects that required embodied cultural capital in order to be appreciated, such as works of art or literature. Institutionalized cultural capital was legitimated cultural capital, often in the form of educational credentials. These forms of cultural capital could be converted to other forms, so that possessing embodied cultural capital enabled an individual to acquire institutionalized cultural capital.

The concept of cultural capital was part of Bourdieu's larger theory of practice, which also included the concepts of habitus (one's worldview or disposition) and field (the context in which social action occurred). Focusing on the educational system, Bourdieu argued that schools operated based on the culture of the dominant class, and expected all students to be knowledgeable of it. While this was true for the middle and upper classes, who were exposed to this culture from birth and throughout childhood in the family setting, the working class and poor students lacked this cultural capital and were at a disadvantage in school. They might not be viewed as favorable by teachers, they might not understand materials or assignments that were based on the dominant culture, and they might opt out of education themselves when seeing the mismatch between their cultural resources and those demanded by the school. Thus, middle and upper class students were more likely to persist in school, attain credentials, and become part of the middle or upper class themselves upon adulthood, reinforcing stratification in society.

However, Bourdieu argued, complete reproduction of the stratification system did not occur. Bourdieu stated that this was a way to keep people believing that success was based on one's ability and effort. In other words, a few students from the lower classes were selected and promoted by teachers, enabling them to succeed, so that others believed that they too had the opportunity to move up the social stratification ladder.

Bourdieu stated that it was possible for members of the lower classes to acquire cultural capital, but it would stand out as different from the cultural capital of the middle classes. For those who were born into privileged families, cultural capital would become second nature, or as Bourdieu described it, embodied, and so it would be used unconsciously by

middle- and upper-class students as they navigated the educational process. On the other hand, individuals whose first acquisition of cultural capital was in the school setting would have more stilted and scholarly cultural capital, and be less able to use it with the ease with which the middle-class students did.

Expansions and Refinements of Bourdieu's Concept and Theory

Bourdieu's definitions of cultural capital varied throughout his works, and so subsequent researchers often had to choose one of his definitions to guide their research, or to come up with their own interpretation of the concept. Paul DiMaggio (1982), one of the earliest empirical cultural capital researchers in the United States, used one of Bourdieu's definitions of cultural capital: "instruments for the appropriation of symbolic wealth socially designated as worth of being sought and possessed." DiMaggio also expanded upon Bourdieu's theoretical argument by bringing in Max Weber's concept of status cultures. DiMaggio, unlike Bourdieu, argued that cultural capital not only served as a tool to reproduce the existing class structure; it also could serve as a vehicle for social mobility for those who were lower in the stratification system. He distinguished between Weber's notion of status group membership and said instead that in the United States, the focus should be on status culture participation. Those who participated in status cultures might be able to ascend the social ladder. Thus, in addition to Bourdieu's cultural reproduction model, DiMaggio introduced a cultural mobility model.

In the late 1980s, Michele Lamont and Annette Lareau published a piece assessing Bourdieu's concept of cultural capital and praised Bourdieu's bringing in of structure to understand the inequalities that occurred in school settings. Based on their readings of Bourdieu's and his colleagues' work, Lamont and Lareau offered a new definition of cultural capital as "institutionalized, i.e., widely shared, high status cultural signals (attitudes, preferences, formal knowledge, behaviors, goods and credentials) used for social and cultural exclusion" (Lamont and Lareau, 1988: p. 156). In a later piece, Kingston (2001) endorsed this definition of cultural capital and added the important qualifier that cultural capital is arbitrary. That is, qualities valued as cultural capital "are not meaningfully related to what schools and work organizations must centrally purport to accomplish, namely, mastery of academic material in schools and productive performance on the job" (90). Thus, the functional skills taught in school were distinct from the elegant turn of phrase or knowledge of obscure literature when teachers evaluated students; the former were the skills that schools were supposed to teach children, while the latter were the mechanisms through which teachers sorted students by cultural capital.

In the early 2000s, Annette Lareau and Elliot Weininger reviewed Bourdieu's writings on cultural capital and also thoroughly examined the 20 years of existing quantitative and qualitative research on cultural capital. Based on their review, they argued that cultural capital should "emphasize(s) micro-interactional processes whereby individuals' strategic use of knowledge, skills, and competence comes into contact with institutionalized standards of evaluation. These specialized skills are transmissible across generations, are subject to monopoly, and may yield advantages or 'profits'" (Lareau and Weininger, 2003: p. 569).

These additional definitions and refinements of the concept of cultural capital are by no means exhaustive, and rely heavily on the United States context. Nevertheless, they share certain traits that point to an underlying coherence in understanding how schools may use cultural differences to perpetuate inequality. The key components of cultural capital thus point to its unequal distribution in society, its ability to provide advantages or open doors for those who possess it and activate it, and its recognition by the dominant institutions of society. The specific ways that cultural capital is measured in empirical research are examined below.

Empirical Cultural Capital Research

Operationalizations of Cultural Capital

Quantitative

Bourdieu's empirical work on cultural capital incorporated many variables on taste, such as respondents' favorite artworks or musical pieces. While the preference for highbrow art was not the only way that Bourdieu measured cultural capital, this approach influenced many subsequent quantitative cultural capital studies, including DiMaggio's work, which in turn set the stage for using arts-related variables in cultural capital research in the United States and other countries.

Quantitative studies are often limited by what is available in the particular data set being used. Some of the more commonly used data sets include the National Education Longitudinal Study (NELS), the Panel Study of Income Dynamics, the Program for International Student Assessment (PISA), the National Longitudinal Survey of Youth, the Family Survey Dutch Population, and the Cultural Capital and Social Exclusion survey from the United Kingdom. Many researchers in different countries also collect their own data via surveys.

Below are some of the more common ways in which quantitative research has operationalized cultural capital:

- Arts lessons: Many quantitative studies (Aschaffenburg and Maas, 1997; DiMaggio, 1982; Dumais, 2002) include whether the student has taken lessons in art, dance, or other forms of the arts. Measures range from simple responses of yes or no, to focusing on the specific ages at which the students took lessons (Aschaffenburg and Maas, 1997). Distinctions are sometimes made between whether the lessons were taken in school or outside of school.
- Attendance at arts events: Researchers have also measured cultural capital using attendance at museums, concerts, or other performances (Roscigno and Ainsworth-Darnell, 1999). Measures range from indicating attendance or not to detailing the frequency of attendance, and again distinctions are sometimes made between school trips and trips outside of school. For some data sets, it is difficult to distinguish whether the two measures described thus far truly tap into highbrow arts or high culture venues, as the survey question may simply ask if the respondent has attended a show or performance, and the questions about music lessons rarely indicate the particular instrument or style of music.

- Reading behavior and books: Reading behavior is used in several quantitative studies. There is some debate over using reading behavior and the presence of books in the home as measures of cultural capital because reading is a skill that is taught in the school setting, rather than a feature of the dominant culture that is inaccessible to the lower classes. Other researchers have argued that reading behavior is a form of cultural capital, particularly when the works being read are of a certain type or when the student is reading books beyond those required for school.
- Educational resources in the home: Jay Teachman (1987) was one of the first American scholars to use educational resources in the home as a form of cultural capital. His measures included the presence of a place to study, reference books, a daily newspaper, and a dictionary/encyclopedia in the home. While Teachman did not explicitly describe his measures as objectified cultural capital, they fit Bourdieu's definition of this concept. Yuxiao Wu (2008) also used educational resources in the home, such as maps and a desk, in studying the relationship between cultural capital and education in China.
- Composite measures: Many researchers have combined different variables into indices of cultural capital. DiMaggio's (1982) operationalization of cultural capital included students' attitudes toward artistic activities and occupations; activities such as creating art, attending performances, reading, or visiting museums; and tests of information about art, literature, and music. More recently, Jun Xu and Gillian Hampden-Thompson (2012), using PISA data, created indices for cultural activities (museum/gallery visits, attendance at ballet or classical concerts, and live theater attendance), cultural communication (discussions of political or social issues, discussions of books, films, or television, and listening to classical music with parents), cultural possessions (works of art, literature, and poetry), and home educational resources (a dictionary, a place to study, a calculator, and textbooks). The authors thus brought together measures of embodied and objectified cultural capital and included parents' influence in the measures.
- Children's vs parents' cultural capital: Some quantitative studies have included cultural capital variables at both the child and parent level. For example, Aschaffenburg and Maas (1997) included measures of cultural training for the respondents and measures of the parents' taste for classical music, as well as whether the parent escorted the child to different cultural events or encouraged reading.

Qualitative

Authors of qualitative studies tend to operationalize cultural capital similarly to the definition given earlier by Lareau and Weininger (2003). Unlike the quantitative studies summarized previously, the qualitative measures of cultural capital rely heavily on parents' behaviors and attributes. For example, Diane Reay (2004) argued that cultural capital was comprised of parents' feelings of confidence and entitlement when interacting with schools, and other qualitative researchers have also analyzed the degree to which parents advocate on behalf of their children in the school and other institutional settings. Possession of information and the ability to use it in a fruitful way has also been described as cultural capital, such as in Patricia McDonough's (1997) study of how parents help their children navigate the college selection and application process. At the student level, some qualitative studies note that cultural capital is demonstrated by the ease with which students interact with strangers or authority figures, and others also mention students' language use as an indicator of cultural capital.

Operationalizations of Educational Outcomes

Quantitative

Much of the quantitative research on cultural capital sets out to accomplish two things: to show that family socioeconomic background is associated with levels of cultural capital, and to show that cultural capital is associated with educational outcomes; often, researchers expect that cultural capital will reduce the direct effect that socioeconomic background has on educational outcomes. Common quantitative educational outcomes are described below:

- Test scores: A common outcome in quantitative studies is students' performance on standardized tests. These are usually tests developed for a specific data set, such as reading or math achievement in NELS, or performance on tests in PISA. In longitudinal studies, prior test scores are often included as controls, so that the outcome being studied reflects gains in achievement.
- Grades: Grades are sometimes preferred over test scores because they include more of a subjective component by teachers, which Bourdieu implied would play a role in social reproduction. Frequently, data sets only offer the students' self-reported grades, but the availability of transcript data in NELS and other data sets allows for an investigation of officially recorded grades.
- Teachers' evaluations of behavior: Some recent research by Susan Dumais (2006) has examined teachers' ratings of students' behavior, including working to one's best ability and one's interpersonal skills, as they are affected by students' cultural capital possession.
- Educational transitions: A number of studies focus on the transitions from lower-level education to higher-level education, particularly in countries where high levels of education are not the norm. In the United States and European countries, many quantitative studies use the transition from high school to college as a dependent variable.
- Degree attainment: The highest degree attained by the respondent is also a measure commonly found in quantitative cultural capital research.

Qualitative

Many of the outcomes detailed in qualitative studies can be categorized as educational advantages. These advantages include a more customized educational experience, placement into gifted programs, help in making the successful transition to the college of one's choice, and a team of parents and other adult authority figures who may advocate on a student's behalf. At the student level, Annette Lareau (2003) focuses on a student's growing sense of entitlement as an outcome of

exposure to cultural capital. This entitlement then enables the student to pursue a variety of opportunities without fear of failure, while students without cultural capital develop a sense of constraint about their lives and future opportunities.

Research Findings

While Bourdieu's research on cultural capital focused on the specific context of the French educational system, researchers throughout the world have applied the concept to their own countries' educational programs, implying that cultural capital is a universal, rather than France-specific, phenomenon. Findings vary by nation and often even within nations, driving more research in order to clarify whether and how cultural capital affects educational success. Many studies also set out to determine the degree to which cultural capital serves to reproduce the existing social structure, or to provide an opportunity for mobility. A few of the major studies from various regions are described below; note that space does not permit all countries to be represented (additional studies not reported here include research on Greece, Kenya, Norway, Russia, and Slovenia, among others).

The Netherlands

Research from the Netherlands on cultural capital has been ongoing since the 1980s and has contributed to the understanding of educational processes in important ways. De Graaf et al. (2000) found that parents' reading behavior during the respondents' childhoods, rather than high arts participation, affected the educational attainment of the adult respondents. They also found that children from less educated families were especially affected by parents' reading behavior, supporting DiMaggio's mobility hypothesis. Kraaykamp and van Eijck (2010) showed that parents' institutionalized cultural capital (years of education) and cultural behavior were positively associated with children's educational attainment, but that the association grew smaller with more recent generations, indicating that the intergenerational transmission of cultural capital may be weakening over time. Finally, while much cultural capital research focuses on family processes, Nagel et al. (2010) examined cultural capital as a required component of an educational program in the Netherlands. They found that there were no long-term effects of participating in the program, either on subsequent cultural participation, or on attitudes toward culture. These findings implied that school interventions may not be effective in enhancing the cultural capital of students beyond what they had already acquired at home.

The United States

Within the United States, DiMaggio (1982) was one of the first researchers to study cultural capital and education. He found both educational and gender differences in the effects of cultural capital on grades for high school students, with males from families with low education benefitting and females from families with high education benefitting. Support thus appeared for both the reproduction and mobility models. In a 1997 piece by Karen Aschaffenburg and Ineke Maas, the authors found that early cultural classes (before age 12) and parents' cultural participation were strongly associated with entering high school, finishing college, and entering college; parents' cultural participation and children's later cultural lessons were associated with finishing college. Additionally, they found some support for the reproduction model, as the transition to college was significantly affected by the interaction of parents' education and child's cultural participation.

Other researchers in the United States have studied the degree to which race and/or gender interact with cultural capital. Susan Dumais (2002) focused on eighth grade students and their self-reported grades, noting differences between males and females. While cultural capital did not have a strong effect overall, it did have a stronger association with grades for females than for males. Roscigno and Ainsworth-Darnell (1999) used data from NELS and examined grade point averages and composite reading and math achievement test scores. They found that not only did the reproduction model work for socioeconomic status, with higher SES students getting greater returns for cultural trips and educational resources, but there was also a reproduction of the racial structure, with white students getting greater returns for their cultural capital than African-American students.

Farkas et al. (1990) were some of the earliest American researchers to employ a mixed quantitative–qualitative approach to understanding cultural capital and schooling. Teachers were given surveys and asked to evaluate students' work habits, disruptive behavior, and appearance and dress. Even after controlling for cognitive performance, students' work habits were an important predictor of course grades, indicating that noncognitive factors affected teachers' perceptions of students.

Additional qualitative research has focused less on academic outcomes, and more on the ways in which cultural capital functions in different settings. Annette Lareau (2003) focused on parenting practices and how they resulted in a sense of entitlement in children. She updated Bourdieu's concepts of cultural capital and habitus to the American context by describing them as a cultural approach to parenting by the middle class, which she deemed as 'concerted cultivation.'

Prudence Carter (2003) coined the term black cultural capital to emphasize that in different contexts, different styles of behavior and dispositions were more advantageous than traditional cultural capital (as defined by Bourdieu) within the black community. Black cultural capital was employed to show authenticity to their peers, while dominant cultural capital was used for success in educational or employment settings.

The research findings for the United States are mixed, but several quantitative studies point to cultural capital as an agent of social reproduction rather than a tool for mobility, and the qualitative studies point to the microlevel interactions that contribute to the reproduction of inequality.

Great Britain

Diane Reay (2004) noted that in England, parental involvement in schooling has become a component of cultural capital. Middle-class mothers in her qualitative study were very confident in debating with and negotiating with teachers, while working-class parents were more apologetic and unsure of themselves, feeling that they did not successfully convey their points of view. Additionally, Reay found that working-class children placed in gifted education often dropped out,

claiming that they did not fit in. In these ways, privilege continued for middle-class parents and their children, while working-class families faced blame because they were less involved or their children did not persist in gifted education. Alice Sullivan (2001) studied four British schools and found that cultural capital, specifically reading activities and watching cultural television programs, was associated with General Certificate of Postsecondary Education (GCSE) attainment. However, these effects disappeared once scores on vocabulary and cultural knowledge tests were included in the model. The findings led Sullivan to conclude that while cultural capital was a useful concept, Bourdieu's overall theory of social reproduction through the schools did not appear to apply to the British context. These two studies (Reay and Sullivan) illustrate the very different findings that can arise from qualitative vs quantitative research on cultural capital.

Asian Countries

Yuxiao Wu (2008) found that cultural capital significantly affected enrollment in junior high school throughout three time periods in China. For senior high school enrollment, cultural capital was not significant during the Cultural Revolution period, and for college enrollment, cultural capital was only significant during the post-Maoist era. The findings thus indicated that the effects of cultural capital were vulnerable to state intervention. Using data from the 2000 PISA, Byun et al. (2012) found an association between socioeconomic status and parental objectified cultural capital, as well as socioeconomic status and children's embodied cultural capital, in South Korea. Only parents' cultural capital, however, was associated with academic achievement. Like Wu (2008), Byun showed that the state's educational system could affect how cultural capital operated.

Yoko Yamamoto and Mary Brinton (2010) studied embodied and objectified cultural capital in Japan and found that fine arts activities were associated both with grades in ninth grade and the quality of high school attended, while objectified cultural capital was associated only with the quality of high school. They argued that fine arts activities built skills that aided in achievement, while objectified cultural capital sent signals to teachers that the students were worthy of being recommended to a more prestigious high school.

International Comparisons

Jun Xu and Gillian Hampden-Thompson (2012) studied 22 countries using PISA data. Despite the increasing educational attainment in different countries and the subsequent opening up of class systems, they found that their measures of cultural capital were moderately correlated with one another as well as with parental education, regardless of the country's regime. Additionally, educational resources at home, cultural communication with parents, cultural participation, and books and works of art in the home were all associated with higher scores on reading-assessment scores. They also found support for the cultural reproduction model in liberal regimes (such as the United States and the United Kingdom), and support for the cultural mobility model in corporatist and Mediterranean regimes. The authors argued that cultural capital remains a salient concept that should continue to be studied across multiple contexts.

Summary of Main Research Findings

Overall, the findings are mixed, although in most of the studies described, cultural capital had a significant association with the educational outcome being studied. However, not all studies found that this translated into the reproduction of inequality through the educational system. Many of the quantitative studies showed a direct effect, or an indirect effect through other variables such as test scores, for cultural capital. The qualitative studies depicted differences in orientations toward schools that resulted in differential rewards for parents and children from different social classes.

Criticisms

There have been several criticisms of the concept of cultural capital, or of its use in research, over the past few decades. One criticism is researchers' use of Paul DiMaggio's cultural mobility model as an explanation for the relationship between cultural capital and school success. As Paul Kingston (2001) argued, Bourdieu's theory of reproduction addressed how the upper classes maintained their position and passed their privileges on to the next generation. To use the mobility model along with the concept of cultural capital could be seen as antithetical to Bourdieu's point about cultural capital and class reproduction. Related to this point is the criticism that Bourdieu's work should not be applied to societies outside of France (and perhaps not outside of the time period during which Bourdieu conducted his study). Kingston (2001) noted that in the United States, there is not an exclusive, dominant cultural group composed of individuals who regularly attend the opera or other highbrow events. Indeed, the rates of cultural participation in highbrow activities are extremely low. How, then, can participation in high culture be argued to represent an exclusive class-based practice that will be used to sort students as they progress through school?

The expansion of the types of variables used to measure cultural capital has also been criticized. As discussed earlier, operationalizations of cultural capital in quantitative research range from arts participation to reading behavior to the presence of a calculator in the home. Not all of these items fit the definitions of cultural capital given earlier by Lamont and Lareau (1988) or Kingston (2001), who respectively emphasized that cultural capital was exclusive and arbitrary. Kingston (2001) argued that even qualitative research has not successfully shown that middle-class parents engaged in exclusive practices that were valued because of their connection to elites. Instead, this research has shown that middle-class parents engaged in practices with their children that were educationally stimulating and thus could be expected to positively affect students' school outcomes.

Annette Lareau and Elliot Weininger (2003) critiqued quantitative cultural capital researchers' tendency to treat cultural capital and ability as conceptually distinct. Reviewing Bourdieu's writing on cultural capital, the authors found no evidence that Bourdieu considered ability to be a separate concept from cultural capital; indeed, his writings indicated that he considered the two to be conjoined. Lareau and Weininger (2003) attributed the frequent separation of cultural capital and ability in quantitative research to a reliance on the status attainment tradition.

Quantitative cultural capital research has been criticized for neglecting to specify the mechanisms by which cultural capital translates into educational outcomes. The lack of mechanisms is often due to the variables available in the data sets analyzed. Furthermore, while Bourdieu's argument implies that teachers play a role in the evaluation and promotion process, many researchers resort to using achievement test scores rather than teacher-based outcome variables. The argument used to justify the use of test scores – that cultural capital enhances students' skills and abilities – relates to the point mentioned above that researchers have tended to consider cultural capital a separate concept from ability.

There have also been some criticisms about the data and methods used to study cultural capital and education. As mentioned earlier, some of the measures in the data sets ask only if the student has ever taken a music lesson, or if the student has attended a concert in the past year. Bourdieu's concept of cultural capital entailed a lifelong exposure to distinctive cultural styles, and so using a single measure of arts attendance may not capture the concept in an adequate way. Additionally, many data sets, such as the Family Survey Dutch Population and the Survey of Public Participation in the Arts, ask retrospective questions about the respondents' childhoods and the behaviors in which their parents engaged during that time. Respondents might not have a clear memory of their parents' cultural participation, or even their own, when it was 15 or 20 years prior. Other data sets are problematic because they are cross-sectional rather than longitudinal, so that measures of cultural capital and of educational outcomes are collected at the same time. It is then very difficult to establish causality. Even longitudinal data may fail to capture the multiple interactions between teachers and students over the course of the school year that result in the teacher's evaluation of the student based on his or her perceived cultural capital.

Future Directions

As research on cultural capital continues, several innovations are occurring that may address the criticisms mentioned in the previous section. For example, S. Michael Gaddis (2013) focuses specifically on the mechanisms through which cultural capital may translate into educational success. His quantitative analyses show that cultural capital affects several psychological variables (which he calls habitus), and that they in turn affect students' grade point averages. Other quantitative studies have also incorporated the concept of habitus, often measuring it as parents' expectations for their children, or the student's expectation for his or her own attainment. Researchers should continue to delve into Bourdieu's work to ascertain what kinds of measures could best explain the link between cultural capital and educational outcomes.

Another important direction, most recently taken by Kraaykamp and van Eijck (2010), is to consider the different components of cultural capital, separately analyzing the effects of the embodied, objectified, and institutionalized states. Kraaykamp and van Eijck's work demonstrates that the intergenerational transmission of cultural capital occurs differently depending on which state is being examined. Yamamoto and Brinton's (2010) work, described earlier, distinguished between two states – embodied and objectified – and found that the mechanisms through which each affected educational outcomes varied, with embodied cultural capital resulting in more skills and objectified cultural capital resulting in better evaluations from teachers. Future research should continue to consider the multiple states of cultural capital and their differential effects on success in school.

The transmission of cultural capital from one generation to another has been a popular research subject, and some scholars are pushing this area forward by analyzing multiple generations, rather than the more common parent–child framework. For example, Josipa Roksa and Daniel Potter (2011) consider the class origins as well as the current class positions of mothers in their analyses of parenting practices and children's academic achievement.

The release of new longitudinal data sets, such as the Early Childhood Longitudinal Study, allows researchers to study the cumulative effects of cultural capital over a period of several years, from the beginning of students' schooling experiences up through their transition to middle school. On the qualitative side, Annette Lareau (2003) conducted a follow-up study with children who were in third grade at the time of the initial study, showing how the cumulative effects of different parenting practices resulted in different pathways toward college or careers for the now young adults.

Cultural Critique, Anthropological

Abstract

Critique is the exercise of judgment. Its roots lie in the Enlightenment's response to the printing revolution. The use of exotic ethnography to shock Westerners out of their complacency is well established. The 1980s saw a vigorous American school of cultural critics at home. They have European, feminist, and Marxist counterparts. Recent developments focus on globalization and cultural diversity. The world culture has become omnipresent and this has diluted anthropologists' attachment to their key concept. It would still pay anthropologists to revisit Rousseau and Kant.

Cultural Critique

Cultural critique, the use of anthropology to draw critical attention to institutions that readers take for granted, is as old as the origins of the modern discipline. It was a major purpose of Boas's students, especially Margaret Mead and Ruth Benedict. Its antecedents range from modernism to the critical theory of the Frankfurt school and the French surrealists between the wars, and the roots of critique lie in eighteenth century philosophy. Cultural critique is a less powerful force today in anthropology than it was in the 1980s, and the lines that separate it from social criticism are more blurred now. As a result, the present article takes a historical view of its subject rather than offering a contemporary survey.

What then is 'cultural critique'? It is to examine the foundations of culture by having recourse to judgment. Judgment in turn is the ability to form an opinion on the basis of careful consideration, beyond that to discern relations linking particulars to more general principles. Although not indifferent to fact and logic, judgment requires consideration of worth. A judge is respected for his or her wisdom and apparent objectivity, that is, for the ability to transcend mere opinion, even by giving expression to universal truth. A cognate expression is critic (which is, after all, derived from the Greek word for judgment). But criticism most often connotes for us the formation of opinions about works of art and the term 'cultural critique' suggests a direct link between anthropology and literary criticism. Indeed, critical anthropology for a time involved a shift in emphasis from life to text, reflecting a trend driven by poststructuralist discourse from the 1970s onward.

The world is currently going through a major transformation, driven by the new digital media, that is social, technological, and cultural in scope. It has fundamental consequences for the human condition and hence for anthropology. The best way to learn about these developments is to take an active part in them. There are analogies between the print revolution and today. For most of human history, information was hard to come by and had to be sought out. With printing, information became omnipresent. This was the origin of critique, since people had to learn how to be selective in what they read. Once choosing not to read something became socially acceptable, the way was open for the mass media. But the relationship between sender and receiver was still asymmetrical. The Internet and especially social media, commonly referred to as Web 2.0, have made available easy-to-use tools that provide a plethora of options for anyone to become engaged with the medium as a communicator in their own right. New social forms adequate to handling this unprecedented freedom of self-expression are at best incipient. They are, moreover, compromised by Web 2.0 being dominated by an outmoded bureaucratic capitalism whose command-and-control system and intellectual property regime continually provoke vigorous demands for more open access to information and for the democratization of its production, distribution, and consumption.

Early Twentieth-Century Ethnography

Ethnography was the dominant form of anthropological enquiry in the twentieth century. It literally means writing about peoples considered to constitute natural units, on the basis of extended participation in and observation of their societies. It arose in opposition to the method that preceded it, evolutionary history. This last sought to explain how the world came to be unified by Western imperialism by postulating a racial hierarchy in which 'our' cultural superiority (having developed a machine technology based on scientific reason) was attributed to biological difference. The First World War undermined the credibility of this claim of Western civilization to be founded on universal reason and opened up a space for anthropologists willing to assert the virtues of ways of life previously considered to be 'primitive' and inferior. Bronislaw Malinowski is rightly considered to be the pioneer of a new ethnographic approach stressing the integrity of contemporary exotic cultures. In *Argonauts of the Western Pacific* (Malinowski, 1961[1922]) he made clear his aim to challenge the assumption that Western economic norms were either universal or inherently superior. Subsequently, Edward Evans-Pritchard drew on liberal myths of Saxon resistance to Norman rule to dispute the identification of political order with the state, finding 'ordered anarchy' among the Nuer of the Sudan (Evans-Pritchard, 1940).

The academic norm of scientific ethnography was made necessary by anthropologists' drive toward legitimacy as a social science discipline. They eschewed fiction of all kinds. The basis of their truth claims was participant observation, the

fact that they had joined the people in some exotic location and shared their life as a means of studying them. Students were encouraged to read the classical monographs as scientific truth. The exercise of judgment was unnecessary, since professional vetting of the empirical object was sufficient guarantee of a monograph's validity. Within this framework of objectivity, ethnography was potentially critical of Western civilization's claim to universality. By stepping out of normal society, ethnographers pointed a sharp light on the assumptions of their readers, showing, for example, that witchcraft accusations made sense or that gifts may be instruments of domination. The general aim of anthropologists at this time seems to have been to discredit the racist assumptions underlying colonial empire. In America, this trend was associated with a position known as 'cultural relativism': every way of life, however barbarous, has a right to exist and it is not for outsiders to judge it as inferior for any reason.

The founder of modern American anthropology, Franz Boas, was himself committed to educating public opinion (Boas, 1929), but his students took this further by setting out to reach a general American audience with the surprising results of their own and others' ethnography. Americans think of their culture as natural, that is, inevitable; by showing them cultural variation elsewhere they are forced to ask if their own culture is malleable. This perhaps accounts for why Ruth Benedict's *Patterns of Culture* (1934), an impressive collation of cultural variety worldwide, was the anthropology bestseller of all time. Its subtitle is particularly instructive: an analysis of *our* social structure as related to *primitive civilizations* (italics added). In *Coming of Age in Samoa* (1928), her colleague Margaret Mead's topic was adolescence. Americans think of teenagers' turbulence as the natural result of sexual development; Samoan youth experienced adolescence more peacefully; so maybe Americans ought to think again about the reasons for teenage behavior. In a comparative work, *Male and Female: a Study of the Sexes in a Changing World* (Mead, 1949), Mead piled example on example to demonstrate that the sexual division of labor thought to be natural in Western societies was a special case. It is not hard to imagine how such a book might enter the campaign for female emancipation. Mead has been subjected to savage criticism of late for the inadequacy of her fieldwork and the exaggeration of her deconstructive cultural contrasts. These attacks have come precisely when the cultural critique she pioneered has sought to undermine the premises of scientific ethnography itself, as she never did.

Cultural Critique in America

More recently, cultural critique in anthropology has been associated with an American school of ethnographers led by George Marcus. With James Clifford he published *Writing Culture: the Poetics and Politics of Ethnography* (Clifford and Marcus, 1986), a book that has come to be seen as marking the postmodern shift in anthropology. At much the same time, Marcus published, with Michael Fischer, *Anthropology as Cultural Critique: an Experimental Moment in the Human Sciences* (Marcus and Fischer, 1999[1986]; see also Marcus, 1999). The growing prominence of cultural critique has been ascribed to a 'literary turn' associated with the work of Clifford Geertz since the early 1970s (Geertz, 1988). Clifford has carved out his own contribution to resolving "the crisis of representation" in a series of works, notably, *The Predicament of Culture* (1988). Paul Rabinow's *Reflections on Fieldwork in Morocco* (Rabinow, 1977) prefigured the critical reassessment of ethnographic method. The journal *Critique of Anthropology* grew out of collaboration between radical anthropologists in Britain, the Netherlands, and the United States, beginning in the 1970s.

The critique launched by *Writing Culture* had as its focus three aspects of the ethnographic enterprise: poetics, politics (both in the subtitle), and epistemology. By 'poetics, attention is drawn to the fact that ethnographers make up what they write. Geertz had been more or less explicit about his ambitions as a creative writer for over a decade before. Language, in such a perspective, is never simply descriptive, but persuasive also. If ethnography is literature, the strident assertion by positivists of its factual (nonfictional) basis must be questioned. The 'politics' of ethnography refers to a triadic relationship between anthropologists, their subjects, and their readers. The political economy of global inequality must be foregrounded in ethnographic descriptions and author/reader relations are more problematic than the original formula allows for. Who are the monographs for and what possibilities for collaboration exist beyond the stereotype of the ethnographer as a lone ranger in a pith helmet? Finally, the status of ethnography as a source of knowledge (epistemology), its methodology, and the configuration of knowledge as power, are called into question. Cultural critique in these terms examines the very intellectual foundations of modern anthropology.

What then have been the poetic and political purposes of the cultural critics and how effective was their epistemological critique? First, they were Americans who wished to engage more directly with American society. That is, they proposed to carry out ethnographic fieldwork in and write about mainstream activities and institutions. This required developing experimental methods, summed up as 'reflexivity, the need for the ethnographer to be continuously self-monitoring in the light of feedback from society. Their aim was similar to Mead's in seeking to disturb conventional assumptions about America's place in the world. Techniques of authorship proved hard to subvert in practice. Although the boundary between fact and fiction became blurred, few anthropologists have openly embraced the novel as a model. The radical rhetoric of the cultural critics, their attempts to develop new constituencies and forms of collaboration ran up against the continuing dominance of the universities as anthropology's institutional home. The ideal of the 'citizen ethnographer, boldly synthesizing fieldwork-based research, critical theory, and political commitment at home, remains a somewhat distant goal. If one can no longer read ethnographies as factual truth, how does one acquire the judgment to make sense of them, especially when cultural relativism has told us one should not judge others as the Victorian imperialists used to? Much postmodern writing adopts an ironic tone and perhaps this is because it straddles unresolved contradictions of this kind. Critics are by definition judgmental, yet convinced relativists have nowhere to stand.

The most controversial aspect of this program is thus its confrontation with the realism, naturalism, and objectification inherent in the positivist tradition of scientific ethnography. The traditional premise of ethnography, the study of other cultures for the sake of our own enlightenment, became more untenable under postcolonial circumstances. It fell to Marcus and his associates to make explicit the faults of a paradigm that had been unraveling for decades. The value of this American movement is much debated. Although the protagonists have sometimes tried to distance themselves from the 'postmodern' tag, preferring to speak of 'high modernism' or 'reflexive modernity, cultural critique has been seen by its positivist detractors as evidence of a postmodern collapse into fragmentation, confusion, and extreme relativism (Gellner, 1992). Others seem to agree that we have entered a postmodern age and that cultural critique is an appropriate response to it.

Cultural Critique in Europe

Cultural critique has not been absent from the other main national traditions of anthropology. Indeed, in France the public's reception of intellectuals has always been readier than was ever the case among the Anglo-Saxons. Moreover, French anthropologists have never embraced a narrow cultural relativism, preferring to keep alive the Enlightenment's legacy of an appeal to universal reason. The publication of Marcel Mauss's political writings (Mauss, 1997) shows how deep seated this public engagement was for him. As his principal successor, Claude Lévi-Strauss wrote a popular classic, *Tristes Tropiques*, and exposed to critical view the central institution of French culture, table manners (Lévi-Strauss, 1976, 1978). Among contemporary anthropologists, Marc Augé has successfully bridged the gap between the academy and popular culture, explaining the symbolic significance of Princess Diana's death and other contemporary events to readers of the serious newspapers.

Augé's contribution to cultural critique has been far-reaching. In *Non-places: Introduction to an anthropology of super-modernity* (1995), the term 'non-place' refers to spaces of transience, such as hotels, airports, motorways, and supermarkets, which are not significant enough to be considered 'places. Starting out as a West African ethnographer, he later turned his attention to Europe and finally to global developments. In the second phase, he applied methods taken from African fieldwork to daily life in Paris. There he drew attention to the absence of a sense of belonging in non-places, the increase in solitude brought about by communication technologies and the erasure of memory. Then, in *An Anthropology for Contemporaneous Worlds* (1998) and *The War of Dreams: exercises in ethno-fiction* (1999), Augé sought to theorize globalization as is lived globally, a reflection in part on his own travels. What is striking about this enterprise is that he exploits the collapse of the fact/fiction pair more fully than the American cultural critics, experimenting with writing techniques such as 'ethnonovels, and he succeeds in renewing anthropology as a whole.

Britain produced the only systematic critique of contemporary civilization by an anthropologist so far in Edmund Leach's prescient British Broadcasting Corporation lectures, *A Runaway World?* (Leach, 1968). There, he identified a world in movement, marked by the interconnectedness of people and things. This provoked the mood of optimism and fear that characterized the 1960s, when established structures seemed to be breaking down. The reality of change could not be understood through conventional cultural categories predicated on stable order. Moral categories based on habits of separation and division could only make the world's movement seem alien and frightening. An ethos of scientific detachment reinforced by binary ideas (right/wrong) lay at the core of society's malaise. Leach called for an intellectual practice based on movement and engagement, connection and dialectic. In short, he was calling for the reinsertion of ideas into life. No one in British social anthropology has come close to this achievement since.

Feminism and Marxism

In the last decades of the twentieth century, feminist anthropology was in the forefront of cultural critique. Indeed, the absence of women from *Writing Culture* provoked a justified response (Behar and Gordon, 1995). After all, the women's movement declared in the 1960s that "the personal is political" and launched a devastating critique of Western institutions on grounds of the invisibility, exclusion, and exploitation of women. These broader criticisms were readily applied to anthropology. An example of the sophistication reached by feminist and postfeminist discourse is Marilyn Strathern's *The Gender of the Gift* (Strathern, 1988), where the confounding of Western gender stereotypes in Melanesian cultures is taken as a point of departure for a much wider critique of such core conceptual pairs as individual/society and nature/culture. The 1980s were a decade of deconstruction, what Hegel called 'negative dialectic, in which the conventional categories of the modern synthesis became confused and discredited. Both inside and outside the academy, this task was performed to a disproportionate extent by women scholars.

Anthropology does not stand alone within an academic division of labor that has recently added Cultural Studies to its ranks. An enhanced focus on the contemporary forms of cultural production has revived interest in the Frankfurt school of Adorno and Benjamin. Their concern with exposing the uses of culture in masking the contradictions of capitalism remains a powerful one. Perhaps even more relevant to critical anthropology is the work of the West Indian Marxist, C.L.R. James (Grimshaw, 1992). Grimshaw and Hart's *Anthropology and the Crisis of the Intellectuals* (1993) placed anthropology's compromised relationship to academic bureaucracy within the general crisis facing modern intellectuals, following James (1993) in *American Civilization*. There he identified a growing conflict between vast anonymous bureaucracies and people's aspirations for an extension of democracy into all areas of their lives, an aspiration that could only be met indirectly through the movies and other forms of popular culture. James saw this as a crisis for modern society as a whole, most acutely revealed in America, and he addressed it through a critique ranging from Hollywood films and comic strips to psychoanalysis and the classical novels of Herman Melville.

For James, the struggle was for individual freedom within new and expanded conceptions of social life (democracy) against a fragmented and repressed subjectivity stifled by coercive bureaucracies (totalitarianism). The intellectuals were caught between the expansion of bureaucracy and the growing presence of people as a force in world society. Unable to recognize that people's lives mattered more than their own ideas, they oscillated between an introspective individualism (psychoanalysis) and service to the ruling powers, whether of the right (fascism) or left (Stalinism). As a result, the traditional role of the intellectual as an independent witness standing for truth had been compromised. The absorption of the bulk of intellectuals into bureaucracy as wage slaves and pensioners not only removed their independence, but also separated their specialized activities from social life.

In Keith Hart's (2005) essay, *The Hit Man's Dilemma* ("Don't take this personal, it's just business") is to be human or inhuman. It is a dilemma shared by kings, generals, presidents, and chief executive officers, when they contemplate the human cost of an action undertaken on behalf of some collective interest. The ability to devise ways of curbing the high-handed behavior of the powerful has been deeply undermined by a legal culture that grants business corporations the rights of living persons. The liberal revolutions against the old regime sought to guarantee citizens equal (and therefore impersonal) rights in society. It meant keeping a clear distinction between individual persons and impersonal institutions. This separation was intrinsic to the rise of modern capitalism. But business corporations sought to collapse the distinction between real and artificial persons in economic law. The impersonal society of the twentieth century flourished on this basis, in the process undermining the idea that ordinary people might exercise personal responsibility in the public sphere. Some intellectuals jumped onto the obvious corruption of liberal ideals to advocate a variety of antiliberal ideologies, drawing on the same confusion of people, ideas, and things that had become normal in law and even in ordinary language.

Ethnicity, Nation-States, and Globalization

John and Jean Comaroff's *Ethnicity Inc.* (2009) highlights a development that seems anomalous in the light of modern social theory, namely, the growing convergence of ethnicity and commerce. They conceive of this phenomenon as a dialectical product of the incorporation of identity and the commodification of culture. Their core case studies are the United States and South Africa, where they live and work. The link to neoliberalism is made explicit, so that the book offers a selective commentary on the subversion of modernity entailed in that movement. Their essay directs attention back to the dual foundation of the nation-state and asks how this proliferation of ethnic brands relates to the nationalist project (and to a parallel commercialization of religion, 'Divinity Inc.'). The Comaroffs thus bring cultural theory up to date by exposing to view a trend that has long historical roots, but is now omnipresent in ways that social science has been slow to recognize because of its own modernist assumptions.

In *Theory from the South* (Comaroff and Comaroff, 2011), they argue that the Global South is rarely seen as a source of theory and explanation for world historical events. Yet the crisis of Northern states encourages a view that they are evolving southward in both positive and problematic ways. They address a range of familiar themes: democracy, law, national borders, labor and capital, religion and the occult, liberalism, and multiculturalism. This view from the South renders key problems of our time at once strange and familiar, giving an ironic twist to the evolutionary pathways long assumed by social scientists.

The line between critique and social theory is increasingly hard to draw in anthropology. But, as this last example shows, much of contemporary critique in the discipline is targeted at globalization. Thomas Hylland Eriksen's (2007) short introduction to the subject is admirably lucid and balanced, but he too has a critical axe to grind. The causes and consequences of globalization are hotly disputed and the book presents a wide range of arguments. Eriksen argues, however, that variation is as characteristic of globalization conceived of as standardization. This dialectical perspective allows him to stress that just as we are being brought closer together by economic and technological developments, the need to differentiate ourselves from each other becomes accordingly that more imperative. This is the reason for an explosion of identity politics of the sort highlighted by the Comaroff and Comaroff (2009), as well as for this often to take overtly commercial or 'neoliberal' forms. Armed with this vision, Eriksen is able to promote some of anthropologists' classical virtues, especially the necessity for a bottom-up, comparative analysis. Distinguishing between the cultural, political, economic, and ecological aspects of globalization, he highlights the implications of globalization for people's everyday lives.

No anthropologist is better known for a cultural approach to the dialectic of nation-states and globalization than Arjun Appadurai. He has formulated concepts that support an anthropological approach to issues such as modernity, globalization, consumption, and public culture. Since these have not traditionally been part of anthropological research, anthropologists have for a long time hesitated to develop tools for dealing with them empirically and theoretically. Appadurai believes that the nation-state is in crisis and hence that current global processes of migration and communication will lead to the deterritorialization of identities in a world that will become culturally hybridized through the growth of diasporic public spheres and the global flow of images, finances, technologies, and ideologies. In *Modernity at Large* (Appadurai, 1996), he suggests one "think beyond the nation, by imagining a form of sovereignty that replaces territoriality with translocal forms. This led his approach to be identified with a 'cosmopolitan' anthropology that was indifferent to local identities.

Appadurai (2006) partially redressed this criticism with the publication of *Fear of Small Numbers* a decade later. Why, in this era of intense globalization, has there been a proliferation of violence, ethnic cleansing, and extreme forms of political violence against civilian populations? Here, he turns his attention to the complex dynamics fueling large-scale, culturally motivated violence, from the genocides that racked

Eastern Europe, Rwanda, and India in the early 1990s to the contemporary 'war on terror. He describes how the nation-state has grown ambivalent about minorities at the same time that minorities, because of global communication technologies and migration flows, increasingly see themselves as parts of powerful global majorities. By exacerbating the inequalities produced by globalization, the volatile relationship between majorities and minorities foments the desire to eradicate cultural difference.

Here is one possible explanation for a contradictory development that has undermined the culture concept and with it cultural critique in recent years. Disciplines outside anthropology turn increasingly to the concept of culture. This is particularly noticeable in certain branches of economics, especially those concerned with development (Rao and Walton, 2004). Joanna Breidenbach and Pál Nyíri (2009) have written engagingly about how culture has become a discursive feature of our world in *Seeing Culture Everywhere*. They conclude with a list of points that they hope will distance them from the more faddish aspects of culture mania. Culture should not be seen as belonging to bounded, homogeneous units. Nor is it unchanging. It is a mistake to imagine that whole cultures could be in conflict with each other or that mixing them up can be dangerous. Uncritical celebration of cultural difference is equally to be avoided. The tendency of neoliberalism to govern through overdrawn stereotypes of 'community' is seen as being a negative development. Cultural pigeonholing is out; cultural creativity at a highly differentiated level is in. One is finally told that ethnography is still a viable method, as long as it is linked to universal notions of 'human development.

Of course, when faced with the popularization of their central concept, anthropologists have started to turn against it. As long as ethnographers reached the remotest corners of the planet, their work could claim to be anthropology in the sense of providing the widest possible context of cross-cultural comparison. It is not easy to see what is anthropological about the indigenous critique of American societies, when the term 'ethnography' is also used by geographers, sociologists, and literary critics. The limitations of cultural critique could be said to lie in two weaknesses. The epistemological critique of ethnographic method has been somewhat introverted, an in-house discourse maintained by a minor academic profession, when the issues involved are potentially of universal significance. And the aspiration to grasp the human condition in general seems to have been abandoned in favor of competing for public attention in the United States. Both these deficiencies might be redressed if critical ethnographers examined their roots in the eighteenth-century philosophy that launched modern anthropology, as well as the notion of critique.

The Roots of Critique in the Enlightenment

This is not the place to explore how Kant developed his original conception of critique, not only most notably in his great *Critique of Pure Reason*, but also, for our purposes, in the *Critique of Judgment* (Cassirer, 1981). In seeking a metaphysical ground between reason and understanding, Kant emulated Copernicus's revolution, showing how, instead of the object revolving around the spectator, the spectator could be seen as revolving, while the object remained at rest. There are so many echoes of Kantian subjectivity in the anthropological moment of cultural critique. What is missing is the as piration to universality of method. This is doubly in excusable in that Kant invented the term 'anthropology' in its modern sense (Kant, 1978). Surely a discipline with the remit of offering knowledgeable guidance on human teleology should not content itself with a jester's role, *épater les bourgeois*.

No one would dispute Jean-Jacques Rousseau's standing as the founder of modern cultural critique. He showed that a critical perspective on society, a refusal to take as inevitable things as they are, requires one to devise new methods of studying and writing about a transitional present. The boundary between fact and fiction has to be blurred if one is to talk about the evolution of possible worlds out of the actual one we live in. In developing a revolutionary critique of politics, education, sexuality, and self-identity (*Le Contrat Social*, *Emile*, *La Nouvelle Héloïse*, and *Les Confessions*), Rousseau came up with a different genre of writing for each topic. Critical anthropologists today might emulate his example, were they not forced to justify themselves to the academic bureaucracy. The two discourses that launched Rousseau's career, however, are the principal sources for a renewal of critical anthropology, combining as they do a critique of corrupt civilization with an anthropology whose aim is to redress global inequality. In particular, his *Discourse on the Origins and Foundation of Inequality among Men* (Rousseau, 1984[1754]), which has inspired anthropologists from Morgan and Engels to Lévi-Strauss, deserves to be seen as the first great work of the modern discipline.

Cultural critique has been an invigorating stimulus to new thinking in anthropology. It is uncertain whether it can flourish while its practitioners remain securely locked up in their academic enclaves. It is time in any case for a return to the universal outlook of the eighteenth-century pioneers. The authors listed toward the end of this article have begun to show how that might be realized.

Abstract

This article provides an overview of the field of cultural evolution, in which cultural change is studied as a Darwinian evolutionary process. Although a fringe interest just 20 years ago, cultural evolution is now a major area of interdisciplinary study. This article outlines the key tenets of cultural evolution theory, describes the main methods used, and highlights outstanding debates and issues that are currently being investigated in the field.

The study of cultural evolution is one of the fastest growing fields in the social and behavioral sciences. In the 1970s and 1980s, cultural evolution was studied by just a handful of scholars at the fringes of traditional disciplines such as anthropology, psychology, and biology. From such small beginnings has spawned a major area of contemporary research. As Figure 1 shows, the number of journal articles self-describing their subject matter as 'cultural evolution' has increased from less than 10 per year in the 1970s and 1980s to well over 100 per year at present. The study of cultural evolution is also unusual in its interdisciplinarity: cultural evolution researchers have an equal chance of having backgrounds in anthropology, archaeology, psychology, biology, economics, and linguistics, and inroads have recently been made into other fields such as history and neuroscience. This article provides an overview of the main theoretical tenets of cultural evolution theory, the primary methods used, the topics studied, and the current controversies within the field, supplementing more detailed articles elsewhere in this volume.

What Is Cultural Evolution?

The answer to this question hinges, naturally, on what one means by both 'culture' and 'evolution.' Although 'culture' has been defined in numerous ways across the social and behavioral sciences (Baldwin et al., 2006), cultural evolution researchers adopt a broad definition along the lines of the following:

> Culture is information that is acquired from other individuals via social transmission mechanisms such as imitation, teaching, or language. (Mesoudi, 2011; pp. 2–3)

This may include beliefs, knowledge, attitudes, skills, preferences, words and grammatical rules, and social norms; essentially, anything that is learned from another individual. Culture can be contrasted with information that is acquired genetically, in the form of parentally inherited sequences of DNA, as well as information that is generated *de novo* by a single individual in isolation, with no social transmission. There is no requirement in this definition that culture be restricted to humans; indeed, many cultural evolution researchers study the cultural capacities of nonhuman species in order to illuminate the evolutionary origins of human cultural evolution (*see* Social Learning and Culture in Nonhuman Organisms). It is also possible for culturally transmitted information to be stored exo-somatically, in external storage devices such as books or computer disks, as well as in brains.

'Evolution' has similarly been defined in various ways during the history of biology (*see* Evolution, History of), although Darwin's conceptualization in *The Origin of Species* (Darwin, 1859) is commonly accepted as the foundational definition within biology. Darwin's theory of evolution comprised three key principles, each of which is necessary for evolution to occur (Lewontin, 1970). There must be (1) variation within a population of entities; (2) competition for survival or reproduction of those entities, for example, due to finite resources; and (3) inheritance of the characteristics of those entities, such that offspring resemble parents more than expected by chance. Darwin demonstrated that these principles applied to populations of organisms. The same principles can be documented for human culture (Mesoudi et al., 2004): (1) there is abundant variation in cultural traits, such as the almost 7000 languages spoken, the 7.7 million technological patents issued, or the 10 000 religious beliefs held in the world today; (2) there is inevitable competition between those traits for memory space, as no one could plausibly speak 7000 languages, understand or use 7.7 million patents, or subscribe to just two different religions at the same time; and (3) cultural traits are reliably passed on to other individuals, as people acquire the languages they speak, the technology they use, the religious beliefs they hold, and so on from other people via social learning. This basic idea that human culture comprises an evolutionary process that fulfills Darwin's definition in *Origin* should be relatively uncontroversial and obvious, and indeed soon after Darwin wrote Origin, he himself noted that the same principles apply to cultural change, primarily linguistic change:

> The formation of different languages and of distinct species, and the proofs that both have been developed through a gradual process, are curiously parallel … The survival or preservation of certain favoured words in the struggle for existence is natural selection. (Darwin, 1871; pp. 90–91)

Two important points should be made here. First, this Darwinian notion of cultural evolution is quite different from

Figure 1 The number of publications with 'cultural evolution' listed as a keyword, 1970–2011. Source: Web of Science.

the theories of social or cultural evolution that were common in anthropology during the late nineteenth century, such as those of Tylor (1871) or Morgan (1877). These theories proposed that entire societies proceed through fixed stages of increasing complexity (e.g., from 'savagery' to 'barbarism' to 'civilization'). These progressive theories are Spencerian, not Darwinian (*see* Evolution, History of). The notion that evolution involves the inevitable progression of species along fixed stages of increasing complexity was long ago shown to be an invalid model of biological evolution (it describes the development of a single organism, not the evolution of a population), and contemporary theories of cultural evolution similarly make no assumptions about the progression of entire societies along developmental stages, focusing instead on how variation changes *within* populations, as did Darwin (Mesoudi, 2011).
